In a Paper recently read before the Société des Ingénieurs Civils, of Paris, on the subject of "Electric Railways with Underground Conductors," M. A. Lavezzari describes an interesting conduit-railway which is projected in Paris. The line will begin at the Place Cadet, near the Porte de Montmartre, and will extend through Rues Cadet, Rochechouart and others, to the end of Rue du Poteau. The road will be 1⅝ miles long, 1⅛ miles of which will be double-tracked, and the remainder single-tracked.

The heaviest grade is only 6 per cent., and occurs in Rue Rochechouart; the other grades average less than 3 per cent. The smallest curve radius is 105ft. The localities traversed are of the most thickly populated in Paris, and those where travel is most active throughout the day, and it is expected that the line will transport 20,000 passengers a day.

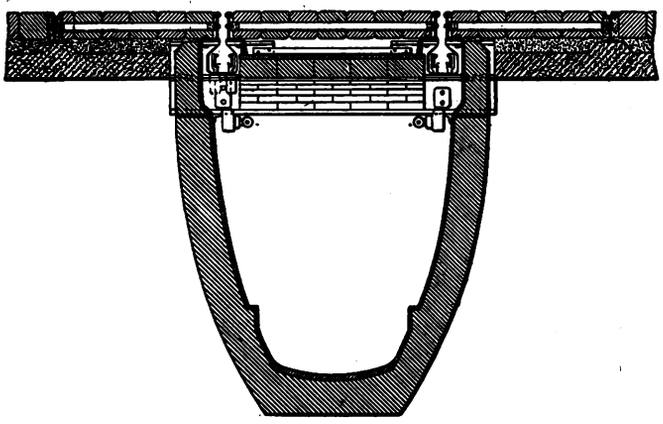
The gauge of the track is one metre (39⅜in.), and on the double-track portion of the line the conduits are arranged as shown. One rail of each track is of the usual girder type, but the other is a modified T-rail, and a similar rail is laid alongside it, with sufficient space between for the passage of the plough. The conductor conduit is located, of course, immediately beneath these rails, and contains both the positive and negative conductors, the rails not being included in the circuit.

The beams rest by means of cast feet on the two side walls of masonry of the main conduit, which is really a large sewer of the usual Parisian type, 5ft. 7in. high under the arch, and provides ready access for the inspection and repair of the conducting system. To facilitate inspection and the transportation of material small trucks may be run along the lower part of the conduit; the track will be formed by two angle-irons set in the masonry.

The transmission of energy between the station and the cars is provided for by two feeders, positive and negative, which are supported in the upper part of the large conduit. These feeders, for perfect separation, are held apart every 13ft. by supporting insulators. Every 328ft. connection is made by branch conductors between the feeders and the working conductors, which latter are of steel and shaped thus:] The branch connections are single conductor flexible cables, provided at one end with pins or shanks which fit in sockets attached to the feeders, permitting ready disconnection when it is desirable to cut out a section of the line.

Digitized by Google

The steel working conductors are supported every 6½ft. by cast arms bolted to the short beams forming the yokes. Double-petticoat porcelain insulators are provided for the conductors. Every 1,000ft. bells or telephone instruments will be installed in the large conduit to place each section of the line in communication with the power station. The collector has the form of a shuttle and rubs against the faces of the steel conductors, contact being maintained by means of springs. The shuttle is flexibly attached to a plough suspended from the car; both are so arranged that in case the car leaves the track they will detach themselves and become disconnected mechanically and electrically from the car without causing damage.



Cross-Section showing Double Track Construction.

The station will contain three engines of 150 H.P. each, coupled by belts or ropes to three 500-volt dynamos, each of 100 kilowatts capacity. The cars will have a capacity, including the platform, of 36 passengers; there will be no top seats. All the cars will be equipped with two motors of 10 H.P. each, but will run in pairs, and the front car will contain all the controlling apparatus, the rear car being provided with motors only.

LONGITUDINAL LIGHT.*

BY G. JAUMANN.

(Concluded from page 657.)

The State τ. Connection between μ and τ.—The magnetic phenomena are connected in the same way with mechanical as are electric phenomena. We may, therefore, repeat the reasoning of the last paragraphs *verbatim*, if instead of electric we deal with magnetic forces, and put μ for ε, and instead of σ we speak of a new physical condition, τ, influenced by the distribution of the magnetic forces.

This gives an equation analogous to (II.'), and this might be taken for the equation required to represent $d\mu/dt$ as a function of the distribution of the magnetic forces. It is correct, indeed, but is *not the equation sought.* From this parallel reasoning we only accept the final equation for the condition of rest of any medium,

$$0=\frac{d}{dz}(\mu_0\mathfrak{X})+\frac{d}{dy}(\mu_0\mathfrak{Y})+\frac{d}{dx}(\mu_0\mathfrak{Z}).$$

As long as we lack proofs—as I know of none—that Maxwell's theory is also insufficient in the magnetic direction, it is not advisable to assume this. However correct it may be to translate the considerations above into magnetic terms, still the choice of the constant corresponding to η_0 is free. This must have the value 1 for all media, and also for rarefied air. *Then μ is independent of the distribution of magnetic forces.*

The assumption of different values for η_0, and the sole value of units for the corresponding magnetic constant amounts to a purely numerical inequality, and corresponds to the notable asymmetry of the known electric and magnetic phenomena.

The electric phenomena are much more varied; there are electric, but not magnetic cathode rays, discharges and chemical phenomena.

The difference of this chapter from the preceding one will show that the present theory is not a merely formal structure, or it would have certainly now lapsed into considerations of symmetry.

Connection between μ and σ.—It does not follow from the remarks contained in the last paragraphs that μ retains a constant value during electromagnetic processes. This cannot be. In that case the constant magnetic forces $\mathfrak{X}_0$, $\mathfrak{Y}_0$, $\mathfrak{Z}_0$ would vanish from equation (I') although we know that constant magnetic forces have a great influence upon the course of the cathode rays.

Wied. Ann., 57, 1, pp. 147—184, 1896.

In reality μ must vary with σ; σ is a physical condition like temperature, pressure, &c. With the temperature all properties of a body change, and also ε and μ. In the same way ε and μ will vary with σ; ε stands, of course, in a different relation to σ from μ, since σ depends upon the electric, but not upon the magnetic forces. But this different relation is expressed in (I.) and (II.), not in (IV.).

The connection between μ and σ is represented by

$$\mu-\mu_0=\nu_0(\sigma-\sigma_0).$$

Here ν_0 is a constant depending upon the nature of the medium, which for dense bodies has the value 1, for rarefied air, according to its decreasing pressure, smaller values, and becomes zero for an absolute vacuum.

Finally we have from (V), (IV), and (II.'):

$$\text{(II.'')}\qquad \frac{a_0}{\eta_0-1}\cdot\frac{\eta_0}{\nu_0}\cdot\frac{du}{dt}=\frac{d}{dx}(\varepsilon_0 X)+\frac{d}{dy}(\varepsilon_0 Y)+\frac{d}{dz}(\varepsilon_0 Z).$$

This is the required equation representing du/dt as a function of the distribution of forces, but not, as expected, of the magnetic, but of the electric distribution of forces.

The reason why the magnetic constant corresponding to η_0 was said to be unity for all bodies, lies in the absence of magnetic cathode rays.

The reason why ν_0 for rarefied air is taken as smaller than 1 is that constant magnetic forces are not without influence upon cathode rays.

IV.—Deductions (Provisionally Communicated).

From the foregoing theory follows the necessity of the appearance of longitudinal electric rays (especially in rarefied air in the presence of large static electric forces), which completely bear the character of cathode rays.

In electro-optics also the theory shows a remarkable agreement.

From the latter field we may gather a large number of new experimental motives, but these will not be discussed until the experiments have been made, for which the means are not at present at my disposal.

Longitudinal Plane Wave. Difference of Species of the Cathode Rays.—Let there be present in a rarefied air space a static electric force Z_0 and no magnetic force. Then an electric longitudinal wave is possible in the z direction. The equations (I.') and (II.') are reduced to

$$\text{(I'3.)}\qquad \varepsilon_0\frac{dZ}{dt}+Z_0\frac{d\varepsilon}{dt}=0,$$

$$\text{(II.')}\qquad \frac{a_0}{\eta_0-1}\frac{d\varepsilon}{dt}=\varepsilon_0\frac{dZ}{dz}.$$

One of the solutions is

$$\text{(a)}\qquad Z=Z_0+C\sin\frac{2\pi}{\tau}\left(t-\frac{z}{c}\right).$$

$$\varepsilon=\varepsilon_0+E\sin\frac{2\pi}{\tau}\left(t-\frac{z}{c}\right).$$

The period τ of these rays is arbitrary, and they superimpose.

The ratio of the amplitudes E and C is

$$\frac{E}{C}=-\frac{\varepsilon_0}{Z_0}.$$

The velocity of propagation c is found to be

$$\text{(3)}\qquad c=\frac{\eta_0-1}{a_0}\cdot Z_0.$$

It follows, from the position of the sines in (a), that propagation takes place in the positive z direction if c is positive. Whether any propagation in that direction takes place depends, therefore, upon whether c in equation (3) has a positive value.

Since η_0-1/a_0 has a definite value, it depends upon the sign of the static electric force Z_0 whether propagation is possible in the positive or negative z direction. Only one of the alternatives is possible, not both, as in the case of transverse waves, when c is determined by a quadratic equation. The longitudinal wave can only, if a_0 is positive, be propagated in the direction of the negative electric force, for η_0-1 has by the foregoing an essentially negative value.

This explains the difference of species of the cathode rays. The necessary limiting conditions* for the excitation of cathode rays, viz., the oscillations of electric forces in the normal to the surface perpendicular to the z direction, are provided by the wire waves

* In 1892 (see above) I specified rapid variations of force normal to the electrode as the condition of excitation of cathode rays. E. Wiedemann has simultaneously arrived at the same conviction on experimental grounds. He says (*Zschr. f. Electro-Chem.*, 8, 1895): "If at the border separating *any* medium from a rarefied gas, rapid variations of potential occur, they give rise to the phenomena usually observed at the cathode in discharge tubes, especially cathode rays, &c.; similar structures appear at the boundary surfaces of differently constituted portions of the same gas, at the boundary of the dark space, at narrow parts of the tube, &c." See also Wiedemann and Ebert, Phys. Med. Soc. in Erlangen, February, 1892.

Digitized by Google

approaching the two electrodes in the same manner. But the cathode rays can only issue from the cathode, for there they have in the outward direction (metal to air) a positive velocity of propagation. At the anode they have a negative velocity outwards, and cannot therefore occur.

η_0 has been shown to have a value very near 1 for dense bodies. Hence the velocity of propagation is very small in dense bodies, and longitudinal rays are difficult to obtain. But as rarefaction proceeds η_0 steadily decreases, so that the velocity of propagation of the cathode rays increases until it attains the limiting value Z_0/a_0 in a vacuum.*

The Blue Cathode Light.—It may be supposed that the blue positive brush light in ordinary air corresponds to the blue cathode light in rarefied air. The latter is known to be an effect of the cathode rays. Then the blue positive glow is an effect of anode rays, which, to judge from their slight thickness and greater luminosity, must have very small velocities of propagation.

From this it may be supposed that η_0 in dense air has a value slightly larger than 1. Accordingly, by (3), only anode rays of small velocity are possible. During rarefaction η_0 falls to 1, then by (3) $c=0$, and no longitudinal waves are possible. As rarefaction proceeds further, η_0 falls belows 1 to 0. These anode rays are excluded, but cathode rays appear, and their velocities of propagation increase with the vacuum. The blue layer appears at the cathode and increases in thickness, while losing in luminosity.

The production of the blue light must be connected with an enfeeblement of the cathode rays. But according to the approximate equations here used (I.′) which obtain for larger static forces, the cathode rays are undamped. Near the cathode, *where the static force preponderates*, the blue light cannot occur. This is in reality a dark space,† which *gradually* passes into the blue light.

At greater distances from the cathode, where the amplitude of the ray does not vanish in comparison with the static form of the field, the equations (I.) apply, which no longer admit sine rays. On entering this region the cathode rays experience an easily-calculable modification and enfeeblement.

Propagation of Longitudinal Rays at an Angle to the Static Force. Transverse Waves.—In rarefied air, also, longitudinal rays are possible, whose wave front is inclined to the direction of the static electric force, and whose direction, as will be shown later on, is perpendicular to the wave front. These rays are, however, not purely longitudinal, but are provided with transverse components. The following equations apply :—

$$\text{(I.′1)} \qquad \varepsilon_0 \frac{d\mathrm{X}}{dt} + \mathrm{X}_0 \frac{d\varepsilon}{dt} - c_0 \frac{d\mathfrak{Y}}{dz} = 0.$$

$$\text{(I.′3)} \qquad \varepsilon_0 \frac{d\mathrm{Z}}{dt} + \mathrm{Z}_0 \frac{d\varepsilon}{dt} + c_0 \frac{d\mathfrak{Y}}{dx} = 0.$$

$$\text{(I.′5)} \qquad \mu_0 \frac{d\mathfrak{Y}}{dt} - c_0 \frac{d\mathrm{X}}{dz} + c_0 \frac{d\mathrm{Z}}{dx} = 0.$$

$$\text{(II.′)} \qquad \frac{a_0}{\eta_0 - 1} \cdot \frac{d\varepsilon}{dt} - \varepsilon_0 \frac{d\mathrm{Z}}{dx} - \varepsilon_0 \frac{d\mathrm{X}}{dx} = 0.$$

One of their solutions is

$$\mathrm{Z} = \mathrm{Z}_0 + \mathrm{C} \sin \frac{2\pi}{\tau}\left(t - \frac{mx+nz}{c}\right).$$

The other three variables X, $\mathfrak{Y}$, and ε are "coherent" and equal-phased, and their amplitudes are proportional to the amplitude c. By putting in this solution we obtain four homogeneous equations for the determination of these amplitudes. The determinant of their coefficients must vanish. This gives the condition

$$(c_0 - \mu_0 \varepsilon_0 c^2) \cdot \left[\frac{a_0}{\eta_0 - 1} \cdot c - (m\,\mathrm{X}_0 + n\,\mathrm{Z}_0)\right] = 0.$$

In wave planes with the direction cosines m and n of the normal we may therefore have three different waves. Two of these correspond to the velocities of propagation

$$c = \pm c_0 \sqrt{\frac{1}{\varepsilon_0 \mu_0}} \left(\frac{d\varepsilon}{dt} = 0\right).$$

In rarefied air also, and in the presence of large static forces, ordinary transverse waves may be propagated in all directions.

The third wave is partly *longitudinal*. It has the velocity

$$\text{(5)} \qquad c = \frac{\eta_0 - 1}{a_0}(m\,\mathrm{X}_0 + n\,\mathrm{Z}_0).$$

This, therefore, is proportional to the cosine of the angle between the total static electric force and the wave normal.‡

Longitudinal rays may therefore not only be propagated in the direction of the negative force, but also at an angle to it, when the velocity decreases. Perpendicularly to the direction of the electric force they have zero velocity. On turning them still further in the direction of the positive force, they are no longer propagated, since their velocity becomes negative.

The insertion of (5) into the amplitude equations shows that these rays have the stronger transverse components, the greater their inclination to the static force. These transverse components lie in the wave surface, the electric transverse component X being in the plane of incidence of the static force, and the magnetic transverse component $\mathfrak{Y}$ at right angles to it.

The condition imposed upon the ray by a normally acting magnetic force, $\mathfrak{Y}_0$, is not without interest. This occurs in equation (I′.5) in the term $+\mathfrak{Y}_0\, d\mu/dt$. It also enters into the determinant, but just in the place where it contributes nothing to its value. Hence the velocity of propagation is not affected by a magnetic force. The transverse components also remain equal-phased, but they alter the ratio of their amplitude to that of the longitudinal component. The total electric vibration is thereby given a different direction with respect to the wave normal. It would not be correct to interpret this in the sense that the magnetic force rotates the direction of electric vibration of the rays, but it means that a ray of such a wave surface, *i.e.* a ray which is not deviated by the magnetic force, is only possible when provided with transverse components under the limiting conditions, such components differing according to the magnitude of the normally acting magnetic force.

Reflection: Inapplicability of Huyghens' Principle.—These rays may be regularly reflected at the bounding plane of another medium, supposing that the static electric force is parallel to the reflecting plane.*

In every other case, especially where the angle of incidence of the rays is smaller than the complement of the angle of incidence of the static electric force, a regular reflection is not possible, for the reason that by equation (5) the velocity of these rays depends upon their direction. This causes the curious phenomenon observed by E. Wiedemann and H. Ebert†, that cathode rays are usually *diffused* by a smooth bounding surface.

The possibility of regular reflection shows that Huyghens' principle does not apply to cathode rays. Equation (5) determines the surface of normals. In this case it is a sphere whose surface, however, passes through the centre of excitation and whose centre lies in the direction of the negative electric force. All the wave surfaces touch the pole to this sphere. Hence, this pole represents the whole Huyghens surface. This would imply that the direction of the rays can only coincide with the direction of the negative force. This is not so, since regular reflection is possible.

In this case, and in the following, the conclusions from Huyghens' principle are in contradiction with the direct calculation from the same fundamental differential equations. Huyghens' principle gives for transverse waves and sound waves, representing a case of the second degree, two solutions—a forward and a backward wave. One of these is right, the other wrong. In this case of the first degree the principle gives only one solution, and that a wrong one.

Sharply defined Cathode Rays.—Limited Transverse Rays.—The cathode rays have, as shown already, a period of about 10^{-9}sec., or much longer than light. In addition, they are longitudinal. It is therefore remarkable that they are not propagated like sound, but in sharply-defined rays like light. Now I can show that just the longitudinal rays of my theory have, with any period, the capacity of yielding sharp rays, while transverse light only yields sharp rays with small wave lengths.

For simplicity the propagation of sharp rays in the direction of the electric force Z_0 only is to be dealt wth. We may then put $X_0 = 0$ in the differential equations. A characteristic solution of these equations, after eliminating $d\varepsilon/dt$, is

$$\text{(6)} \qquad \begin{cases} \mathrm{Z} = \mathrm{Z}_0 + \mathrm{C} \sin \dfrac{2\pi}{\kappa} x \,.\, \sin \dfrac{2\pi}{\tau}\left(t - \dfrac{z}{c}\right), \\ \mathrm{X} = \quad \mathrm{A} \cos \dfrac{2\pi}{\kappa} x \,.\, \cos \dfrac{2\pi}{\tau}\left(t - \dfrac{z}{c}\right), \\ \mathfrak{Y} = \quad \mathfrak{B} \cos \dfrac{2\pi}{\kappa} x \,.\, \cos \dfrac{2\pi}{\tau}\left(t - \dfrac{z}{c}\right). \end{cases}$$

This represents a ray of infinite wave surfce z=constant, whose direction is x=constant, since its intensity changes in the direction x. This change with x is sinusoidal.

* The velocity of longitudinal elastic waves in a compressible medium changes in the reverse order—viz., between ∞ and 0.

† This and the blue light space must not be confounded with the dark space sharply marked off towards the blue end of the discharge.

‡ H. Poincaré has shown (*C. R.*, December, 1895), that the rays of my theory follow this law of velocity under all circumstances. His conclusion that on that account the direction of these rays always coincides with the statical force is inadmissible.

* They also penetrate into the new medium, *e.g.* glass, and freely at normal incidence, but are subject to great absorption, not in the interior of the glass, but at the surface. This is easily calculated from the energy equation (III.), allowance being made for the change of η_0 in the surface layer from 0 to 1 nearly. Cp. observations by Wiedemann and Ebert.

† Phys. Med. Soc. Erlangen, December, 1891.

Digitized by Google

The determinant of coefficients of the amplitude equation comes out as

$$(7) \qquad \left[c_0^2 - \left(\varepsilon_0\mu_0 - c_0^2\frac{\tau^2}{\kappa^2}\right)c_2\right]\cdot\left(c - \frac{\eta_0 - 1}{a_0}Z_0\right) = 0.$$

There are again three solutions. In the first place, a longitudinal wave of the velocity of propagation

$$c = \frac{\eta_0 - 1}{a_0}Z_0$$

is possible. Hence the sinusoidal distribution of the intensity in the section of the ray does not change its velocity of propagation. We may, therefore, assign any value to the width of strips κ in solution (6), and on composing a series of such solutions by Fourier's theorem we obtain the following thesis :—

Longitudinal rays of small amplitude are possible with any distribution of intensity in their section, and therefore also with a sharply-defined section without limiting conditions, for any period, and they have the normal velocity of cathode rays.—As seen from equation (6), there are no transverse components at the centre of a limited cathode ray, but they occur towards the edges (a radial electric and a tangential magnetic component), and they are displaced with respect to the longitudinal vibration to the extent of a quarter wave length.

Further, we obtain from (7) the two velocities of propagation

$$c = \pm c_0\sqrt{\frac{1}{\varepsilon_0\mu_0 - c_0^2\frac{\tau^2}{\kappa^2}}}.$$

These correspond to transverse rays with a sinusoidal distribution of intensity in the section. If $c_0\tau/\kappa$ does not vanish, *i.e.*, if the cross-division is of the order of the wave-length of the ray, these rays have not the normal velocity of propagation of the transverse rays.

We can therefore only compound a series of such rays of different width κ by Fourier's theorem to a sharply-defined pencil, when their sectional area is large in comparison with the wave-length.

Hence *transverse rays must always be ill-defined at the edges.* As seen by (6), *longitudinal light occurs at the edge of every transverse light ray* (even in air at ordinary pressures), and is displaced by a quarter wave-length with respect to the transverse portion.

Rotation of the Wave Surface by a Perpendicular Magnetic Force.—A pure longitudinal wave of infinite wave-surface under the influence of a perpendicular magnetic force only retains the direction of its electric oscillation, and has no need of a transverse magnetic component *if the wave surface rotates under the influence of the magnetic force.*

This follows from the equations

$$(I.'3) \qquad \varepsilon_0\frac{dZ}{dt} + Z_0\frac{d\varepsilon}{dt} = 0.$$

$$(I.'5) \qquad \mathfrak{Y}_0\frac{d\mu}{dt} + c_0\frac{dZ}{dx} = 0.$$

$$(II.') \qquad \frac{a_0}{\eta_0 - 1}\cdot\frac{d\varepsilon}{dt} - \varepsilon_0\frac{dZ}{dz} = 0.$$

$$(II.'') \qquad \frac{a_0}{\eta_0 - 1}\cdot\frac{\nu_0}{\nu_0}\cdot\frac{d\mu}{dt} - \varepsilon_0\frac{dZ}{dz} = 0.$$

Their solution is

$$Z = Z_0 + C\sin\frac{2\pi}{\tau}\left(t - \frac{mx + nz}{c}\right).$$

$$\varepsilon = \varepsilon_0 + E\sin\frac{2\pi}{\tau}\left(t - \frac{mx + nz}{c}\right).$$

For the cotangent of the angle of rotation of the wave surface we have

$$-\frac{m}{n} = \frac{\nu_0}{\eta_0}\cdot\frac{\eta_0 - 1}{a_0}\cdot\frac{\varepsilon_0}{c_0}\mathfrak{Y}_0.$$

Let the positive z direction be from left to right, and in this direction let the cathode ray proceed. Let the positive x direction go downwards, then the positive y direction will be towards us. When $\mathfrak{Y}_0$ is positive, the wave normal, by (8), is deflected *upwards.* This is the sense in which the direction of a cathode ray is known to be deflected by a perpendicular magnetic force. The following calculation will show that the direction of the ray and the wave normal are indeed identical.

Magnetic Deflection of the Cathode Rays.—Let us investigate the conditions under which a cathode ray describes a circularly curved path. This will, of course, only be possible approximately and for a short portion of its path. If a perpendicular magnetic force exists, a bent cathode ray is the simplest integral of equations (I.') and (II.'), and the only one which is consistent with the limiting conditions.

The equations shall be transformed to cylindrical co-ordinates, and let y denote the axial direction, x the radial direction, and ζ the polar angle. Let Z be the tangential, X the radial component of the electric force, $\mathfrak{Y}_0$ the axial magnetic force.

The equations are to be reduced to

$$(I.'1) \qquad \varepsilon_0\frac{dX}{dt} + X_0\frac{d\varepsilon}{dt} = 0.$$

$$(I.'3) \qquad \varepsilon_0\frac{dZ}{dt} + Z_0\frac{d\varepsilon}{dt} = 0.$$

$$(I.'5) \qquad \mathfrak{Y}_0\frac{d\mu}{dt} = c_0\frac{dX}{x\,d\zeta} - c_0\frac{dZ}{dx} - c_0\frac{Z}{x}.$$

$$(II.') \qquad \frac{a_0}{\eta_0 - 1}\cdot\frac{d\varepsilon}{dt} = \varepsilon_0\frac{dX}{dx} + \varepsilon_0\frac{X}{x} + \frac{\varepsilon_0}{x}\cdot\frac{dZ}{d\zeta}.$$

$$(II.'') \qquad \frac{\eta_0}{\nu_0}\cdot\frac{d\mu}{dt} = \frac{d\varepsilon}{dt}.$$

We only consider a thin pencil of the cathode ray, whose thickness $(x - x_0)$ vanishes in comparison with the radius of curvature x_0. The simplest solution is the following :—

$$Z = Z_0 + C\left(1 - \frac{x - x_0}{x_0}\right)\sin\frac{2\pi}{\tau}\left(t - \frac{\zeta}{w}\right),$$

$$X = X_0 + A\left(1 - \frac{x - x_0}{x_0}\right)\sin\frac{2\pi}{\tau}\left(t - \frac{\zeta}{w}\right).$$

The intensity of the ray somewhat decreases towards its convex side. The wave surfaces ζ = const. are radial. For the angular velocity w of the ray we have here only one solution.

$$(9) \qquad w = \frac{1}{x_0}\cdot\frac{\eta_0 - 1}{a_0}\cdot Z_0.$$

This solution applies to longitudinal rays. Transverse rays with this course are not possible, and cannot appear as a solution for the simple reason that no magnetic transverse component is provided for.

Further, we have, for the amplitudes A and C, the relation

$$(10) \qquad \frac{A}{C} = \frac{X_0}{Z_0}$$

i.e., the electric oscillations of the ray take place in every part of it in the direction there followed by the static electric force. Finally, we have

$$(11) \qquad \mathfrak{Y}_0 = \frac{\eta_0}{\nu_0}\cdot\frac{c_0}{\varepsilon_0}\cdot\frac{a_0}{\eta_0 - 1}\cdot\frac{X_0}{Z_0}.$$

This is the condition governing the circular form of the ray. If $X_0 = 0$, and therefore the total electric force has a circular path in any case, then by (11) $\mathfrak{Y}_0 = 0$, *i.e.*, the ray follows accurately a curved electric tube of force, unless deflected by a perpendicular magnetic force.

We may therefore attribute to cathode rays of small amplitude having no magnetic transverse components the tendency to follow the electric lines of force of the field, and hence to show electric deflection.*

Cathode rays, provided by the limiting conditions with magnetic transverse components, are more independent of the course of the lines of force, as far as their direction is concerned. This applies even more to cathode rays of high amplitude.

But supposing X_0 is not zero, and the electric force is not circular, then, by (11) a perpendicular magnetic force is necessary in order to deflect the ray from the electric tube of force into the circular path. The sense of the deflection results in the same way as before. The rotation of the wave surface by a magnetic force is, in fact, the same phenomenon as the curvature of the ray now dealt with.

But by (10) the direction of oscillation of the magnetically-curved ray is not influenced by the magnetic force, but takes place as usual in the direction of the electric force.†

The thin bent pencil of a cathode ray here considered corresponds to the axial portion of a limited cathode ray of greater thickness. The edges are more complicated, since they contain magnetic transverse components. Strictly speaking, there will be a magnetic transverse component also in the axial pencil at the points of strong deflection, caused by the change of the amplitude A by (10). This is, however, negligible owing to the short period of oscillation of the ray.

The accompanying figure (p. 688) represents graphically the behaviour of a cathode ray in a homogeneous electric field when deflected by a perpendicular magnetic force.

The parallel arrows proceeding from right to left denote the positive direction of the electric force. The strength of the magnetic force $\mathfrak{Y}_0$, which points from front to back, is indicated

* Huyghens' principle here represents the direction of the ray exceptionally well, but not the situation of the wave surface.

† Hertz compares the magnetic curvature of the cathode rays with the magnetic rotation of the plane of vibration of light. However characteristic this comparison may be, yet by the present theory it is exactly contrary to the actual conditions. This is an accidental circumstance which does not detract from the merit of the comparison.

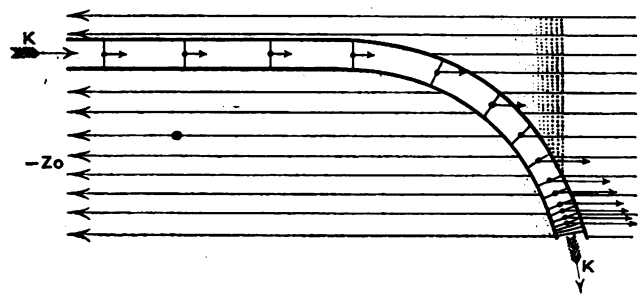
Digitized by Google

by the density of the dots. It is taken as very small in the left portion of the field, and as increasing towards the right, so that by (11) the ray is more and more strongly deflected, and follows a nearly circular path.

The cathode ray K K is rectilinear in the left-hand portion of the field, where no magnetic force acts, and runs in the direction of the negative electric force, whereas it bends away from this direction in the right-hand portion. By equation (11) the tangent of the angle between its direction and that of the negative electric force is everywhere proportional to the force $\mathfrak{Y}_0$.

Furthermore, the wave surfaces of the ray, everywhere at right angles to its direction, are entered, at such distances as correspond to the velocities of propagation of the ray. They decrease by (9) with the cosine of the angle of deflection. In the centre of each wave surface the electric oscillations of the ray are represented in direction and magnitude by an arrow. They preserve their direction in a homogeneous electric field. The magnitude of the longitudinal component c will be approximately the same along the whole course of the ray. But the radial component A must increase considerably by (10). Hence the intensity of the total oscillation of the ray must increase in proportion as the ray is deflected. But at the same time the velocity of the ray decreases, so that the amount of energy contained in a semi-wave length of the ray has everywhere the same value.

Mutual Repulsion of Cathode Rays.—The equations (I.), which apply to cathode rays of high amplitude, are capable of representing the mutual repulsion of two cathode rays. This is a non-superimposing phenomenon, and cannot therefore be explained by the approximate linear equations (I.'), but may be explained by the non-linear equations (I.). Let electric Z-oscillations be given as limiting conditions in the $x\,y$ plane, as they take place at the two cathodes of the Crookes tube. The integral of the equations (1) will then in any case represent two rays proceeding from these plates, and, by their non-linear form, not rectilinear rays, but approximately hyperbolic rays diverging from each other.



Graphic Representation of a Cathode Ray in a homogeneous electric field when deflected by a perpendicular magnetic force.

Magnetic Longitudinal Rays.—Purely magnetic longitudinal rays are impossible, owing to the asymmetry of equations (II.') and (II.").

An electric cathode ray proceeding in the direction of an electric and a coincident magnetic line of force shows, besides its electric longitudinal vibration Z, also a magnetic longitudinal vibration, $\mathfrak{Z}$.

This might conceivably have an indirect effect upon a coil along whose axis a ray proceeded. Such an experiment would occupy a special position among radiation experiments.*

V.—Longitudinal Light.

Longitudinal Portions of Ordinary Light.—As already shown, transverse light is accompanied (in dense air at its edges, at least) by *longitudinal rays*, which are coherent and displaced by a quarter wave-length with respect to the transverse light. In what follows, such longitudinal portions of natural light are proved to exist by Elster and Geitel's experiments.

For the detailed study of these, a closer investigation is necessary of the transition of light across a surface in which ϵ_0 and η_0 are changed. Such a layer occurs where the light enters rarefied air, and where it is reflected by it. In these bounding strata the light assumes longitudinal components. To give an only approximately valid example, we will suppose that the forces of the transverse ray fulfil Laplace's equation in this terminal layer also, and that η_0 is not unity in it, but constant.

Then equation (II.') holds good and assumes the form

$$(12) \qquad \frac{a_0}{\eta_0 - 1} \cdot \frac{d\,\varepsilon}{d\,t} = X\frac{d\,\epsilon_0}{d\,x} + Y\frac{d\,\epsilon_0}{d\,y} + Z\frac{d\,\epsilon_0}{d\,z}.$$

When the direction of the electrical oscillations of the transverse ray is perpendicular to the direction of the fall of ϵ_0, and then only, is $d\,\varepsilon/d\,t = 0$ and no longitudinal rays are formed.

The longitudinal vibrations formed have, as is evident on comparing (12) with (I.') a difference of phase of a quarter-wave length with respect to the transverse vibrations X, Y, Z. They have in fact the same phase as ϵ.

Elster and Geitel's Measurements.—When I received the recent work by Elster and Geitel* I saw at once that in their discharge experiments partly longitudinal light occurs, and that it has a phase displacement of a quarter-wave length with respect to the transverse light.†

This follows from my discharge layer by the first chapter, and is thus a purely experimental conclusion.

The photoelectric current J is by Elster and Geitel proportional to the intensity of illumination (*i.e.*, the square of the amplitude) and follows the law $J = A\cos^2 a + B\sin^2 a$, where a is the azimuth of the plane of electric oscillation of the light with respect to the plane of incidence. The constants A and B have the following values:—

Angle of incidence i.	70°	66°	40°	23°
A	149·6	144·0	161·3	96·8
B	3·2	4·0	7·1	28·1

In the form $J = (A - B)\cos^2 a + B$

the equation shows that B (the deviation from my prediction) is very small for large angles of incidence, but increases strongly at small angles.

With a constant angle of incidence, and variable azimuth, the light shows a *constant* deviation B from the effect it ought to have if my discharge law were right and the light were purely transverse.

Hence the light has a longitudinal component, and this is displaced by a quarter wave-length. Then the squares of the vibrations sent by the transverse and the longitudinal vibration of the light respectively into the electrode normal, will be added to form the square of the resultant vibration in the normal, which determines the photoelectric effect.

B stands to the amplitude L of the longitudinal vibration in the relation

$$B = L^2\cos^2 i.$$

(A − B) has the following relation to the amplitude T of the transverse vibration:—

$$(A - B) = T^2\sin^2 i.$$

This gives

$$\frac{L}{T} = \tan i\,\sqrt{\frac{B}{A - B}}.$$

From the results of measurements by Elster and Geitel we therefore have

Angle of incidence i.	70°	66°	40°	23°
$\frac{L}{T}$	0·411	0·381	0·181	0·275

Although the intensity of the light used at various angles of incidence was not the same, there is a fairly regular decrease of the ratio of the longitudinal portion L of the light and its exciting transverse amplitude T with the angle of incidence, which might complete the agreement with the theory.

The transverse light shows longitudinal components, whose phase is displaced by a quarter wave length, whose amplitude decreases with the angle of incidence, and which, in the measurements quoted, amount to about a third of the transverse amplitude.

Since then Messrs. Elster and Geitel have published figures,‡ from which it would appear that only in rarefied air these longitudinal portions have a considerable magnitude, as was to be expected.

The Society for the Advancement of German Science, Art and Literature in Bohemia has aided the completion of this work, for which I hereby express my thanks.§

* If Maxwell's equations (I.) are rigidly valid, the magnetic longitudinal ray could not indicate itself by an induction effect; but any small deviation from these equations would make that possible.

* "Dependence of the Electric Current upon the Azimuth and Angle of Incidence of Light" (*Berl. Ber.* p. 209, 1895, *The Electrician*, Vol. XXXV, p. 272.

† Elster and Geitel do not recognise that they have to do with longitudinal light, but assume that light vibrating parallel to the cathode surface also favours discharge. See *The Electrician* above, p. 629, first note.

‡ *Wied. Ann.*, 55, p. 695, 1895.

§ The following letter has just been received from Prof. Jaumann:—"Sir, I have been very pleased to see my Paper translated in your most esteemed journal, and I beg you to give a place to the following remark: My Paper bearing the title 'Longitudinal Light' was published for the first time in the *Sitzungsberichte* of the Imperial Academy of Science of Vienna, on July 4, 1895, that is five months before the celebrated Paper of Prof. Röntgen was published. I should like, too, to call attention to a Paper delivered by Prof. E. Dorn at the Naturforschende Gesellschaft of Halle February 27, 1896, where he shows—by investigating the discharging power of X-rays at various angles of incidence and with the aid of my law of discharges—that the X-rays are *sensibly transversal*.—I am, sir, yours truly, G. Jaumann, German University of Prague, March 17 1896."

PHYSICAL SOCIETY.

At an ordinary meeting of the Physical Society held on March 13, 1896, Prof. Carey Foster (Vice-President) in the chair,

Mr. J. H. REEVES read a Paper on

"An Addition to the Wheatstone's Bridge for the Determination of Low Resistances."

The piece of apparatus described can be used for measuring the resistance of metre lengths of wires of low resistance, the only additional apparatus required being a sensitive galvanometer, a Post Office form of resistance box, and a metre bridge. It differs from the ordinary Kelvin bridge in that instead of balancing by varying the length of the standard wire between the two contacts, the distance between these contacts is maintained constant, as is also the length of the wire which is being measured, and balance is obtained by altering other resistances in the network. The author has made a number of tests which show that by his arrangement the resistance of metre lengths of copper wires between the limits of No. 22 S.W.G. and a stranded cable of seven No. 16's can be determined with an accuracy of 0·1 per cent.

Mr. REEVES also read a note on

"The Exact Value of Matthiessen's Standard."

Prof. A. GRAY (communicated) said that the author had in his arrangement combined the fixed standard employed in Matthiessen and Hocking's modification of the ordinary bridge with the greater celerity of working arising from the smaller number of operations to be performed when the Kelvin bridge is used. Prof. Gray thinks that he, and probably others, have used a method similar to that of Mr. Reeves, but that the Paper is of great utility, since it shows how time may be saved and existing apparatus utilised.

Prof. AYRTON said that the advantage of the method described lay in the fact that it was independent of the resistances at the contacts. In Carey Foster's method, however, the coils had to be interchanged and inaccuracy might be introduced owing to the varying resistance of the mercury contacts. Unless the mercury cups and the copper plates at the bottom were cleaned every day, and the contacts re-amalgamated, the resistance of the mercury cups was very variable. With regard to the question of Matthiessen's standard it is to be remembered that the specific conductivity of copper has been steadily increasing. This increase was particularly noticeable in the copper prepared by the Elmore process, where during the deposition of the metal an agate burnisher is kept continually passing over the surface. Fitzpatrick had explained the rise in conductivity of copper by supposing that the density of the copper now supplied was greater than that of the copper used by Matthiessen, and this explanation seemed quite satisfactory. Mr. Reeves's experiments, however, have conclusively shown that this is not the true explanation. It was now possible to obtain copper in large quantity, having a conductivity of 103 on Matthiessen's scale.

The CHAIRMAN (Prof. Carey Foster) explained how, when using his method, the accuracy of the result depends not on the elimination of the small resistances at the mercury cups but on the constancy of these resistances. Matthiessen and Dr. Russell found that the specific gravity of copper was apt to be low on account of the presence of dissolved oxide, and they were the first to pass hydrogen gas through the molten metal to remove this oxide.

Mr. APPLEYARD gave a simple diagrammatic sketch of the author's arrangement, and also pointed out that better results would probably be obtained with a galvanometer of 1 or 2 ohms resistance.

Mr. CAMPBELL said that it ought to be definitely settled whether Matthiessen's standard was the conductivity per unit volume or per unit mass. Since copper was always bought by weight, he, as a practical man, strongly advocated the adoption of the mass conductivity, for in this case the measurement of the specific gravity would be avoided.

Mr. REEVES having replied, a communication by Herr PULUJ, on

"Cathode Rays,"

was read by the secretary.

Herr Puluj contributed some Röntgen photographs, taken by means of a form of Crookes tube which he had described in a memoir published in 1889. With this tube he has succeeded in obtaining impressions with exposures of only 2sec. Herr Puluj considers that the particles of matter torn from the cathode, which convey negative electrostatic charges, by impact on the glass walls or on screens equalise their electric charges, and in this process call forth not merely a disturbance of the material molecules but also of their ether envelopes. Each portion of the glass or screen bombarded by the cathode stream becomes the starting point of ether waves, which, according to their oscillation period and oscillation character, are either visible rays (phosphorescence) or invisible Röntgen rays. The oscillations of the invisible rays may take place in the longitudinal direction, but no convincing argument has up to now been brought forward to support this view.

The SECRETARY also read a note on

"Permeability to Röntgen Rays,"

by Messrs. Ackroyd and Knowles.

The authors have exposed a plate on which a number of pieces of metal, oxides and sulphates were placed to the Röntgen rays in order to see whether the permeability of bodies to these rays depends on the atomic or molecular weight of the body. In each case it was found that the opacity increased with the molecular weight.

Mr. BLAKESLEY said that he considered the Röntgen rays to be the propagation of electrostatic strain through space. With reference to the non-refrangibility of these rays, he had observed in one of the photographs exhibited by Mr. Swinton a dark line at the edge of the shadow of a wooden pencil, which might have been due to the refraction of the rays thrown by the wood. Mr. Blakesley has, however, found that this line is due to the varnish on the pencil. Some Röntgen photographs of quartz and ebonite rods not only did not exhibit these dark lines, but there was a very slight indication of a bright line just on the edge of the shadow which would indicate that the refraction of these rays was less in the rods than in the surrounding medium.

Mr. EDSER exhibited some photographs taken with Mr. Jackson's form of tube, in which a concave cathode is employed. Mr. Edser said that the whole of the tube on the cathode side of the anode plate phosphoresced, so that the Röntgen rays seem to partake of the character of diffused light.

Prof. AYRTON said Mr. Jackson had found that the cathode rays form a parallel beam, and do not first come to a focus and then again spread out.

The CHAIRMAN said that some observations made by Mr. Porter agreed with those of Mr. Edser.

Mr. BLAKESLEY described the tube used by Puluj, in which a mica screen coated with green calcium sulphide is placed between the cathode and the anode.

Mr. GARDNER said that there seemed to be some confusion, for where a concave cathode is employed the cathode rays are brought to a focus and then again diverge. The phosphorescence on the inside of the glass had been shown by Lenard to be due to electricity travelling round the inside surface of the glass.

Mr. PIDJEON asked if any one had tried the effect of mounting the photographic film on a metal plate.

The CHAIRMAN said that Captain Abney had found that if the film was mounted on a ferrotype plate no action took place.

Prof. PERRY said that he for one was of opinion that the Röntgen rays were undulatory. Prof. Larmor had given an explanation which seems to agree with the observed facts. This explanation supposes that the intermolecular spaces respond to vibrations of a certain frequency. The reason no refraction or diffraction effects had been observed was probably because of the extreme smallness of the wave length of the undulation.

After some further remarks, the Society adjourned till the 27th March.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, March 20th.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.

7:40 p.m. General Meeting in the Lecture Hall of the Subscription Literary Society, Fawcett-street, Sunderland. Papers to be read: (1) "The Determination of the Forces which produce Vibration with Three-Crank Engines at High Speeds." by R. M. Ferrier; (2) "Balancing High-Speed Engines," by A. E. Doxford.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting in the Library of the Institution. Paper to be read: "Some Distinctive Features of Continental Engineering Practice," by K. Edgcumbe and E. J. Fox.

SATURDAY, March 21st.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture (V.): "Light," by the Right Hon. Lord Rayleigh, F.R.S.

MONDAY, March 23rd.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting at the Palatine Hotel, Hunt's Bank, Manchester. Paper to be read: "The Regulation of Pressure and the Reduction of Light Load Losses in Alternating Current Systems of Electric Light," by E. W. Cowan.

TUESDAY, March 24th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read: "The Thermal Efficiency of Steam Engines." by Captain H. Riall Sankey.

THURSDAY, March 26th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be read "Telephone Exchanges and their Working," by Dane Sinclair.

FRIDAY, March 27th.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at St. James's Hall Restaurant.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "New Researches on Liquid Air," by Prof. Dewar.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

HE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s.; abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*Nearly ready.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field: Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; Dr. Heinrich Hertz; Mr. R. E. B. Crompton; and William Sturgeon have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)

ILLEGAL STREET MAINS.

We have on some previous occasions recommended those who are interested in the electric supply business to study the ancient history relating to gas companies. The privileges accorded to these pioneers of public lighting have been regarded with a good deal of jealousy by electrical engineers, but it should be some compensation to them that they are able to obtain gratis the benefit of the experience upon various knotty questions which their predecessors have purchased at considerable cost. Thus when electric light men are in difficulty as to their rights or obligations under untried circumstances, a precedent can often be found in the records of gas companies, which, if it does not exactly fit the case, will at least afford a useful guide to assist in arriving at a right conclusion.

In the year 1852, when gas enterprise was in full swing, the town of Sheffield had for a good many years enjoyed the services of a gas company duly constituted by Act of Parliament, and having a large system of street mains. Whether they supplied indifferent gas, or their charges were higher than Yorkshiremen felt called upon to submit to, we know not, but there sprang up somehow a new company, a thing of altogether heterodox origin, unknown to Parliament, and owning no subjection to the Gas Works Clauses Act. But notwithstanding these defects this upstart company so gained the favour of the shrewd people of Sheffield that the Board of Surveyors of Highways, the then ruling authority of its streets, decreed that this free lance should be permitted to tilt at the orthodox purveyor of gas by laying mains in the streets to the extent of some 70

Digitized by Google

miles or more. This was clearly a case for the grand inquisitor in the person of the ATTORNEY GENERAL, who was at once put in motion by the champions of the true faith bent on preventing misguided consumers from being perverted from their due allegiance. The thing was clearly illegal, the Highway Board had exceeded its powers. If a great many, possibly a majority, of the ratepayers were so blind as not to perceive that a serious public nuisance was caused by pulling up streets for laying and repairing mains, where none but Parliamentary mains should be, there was still a guardian of their better principles large hearted enough to spend money in order to safeguard public rights. The suit of Attorney General *v.* The Sheffield Gas Consumers Company, 22 *Law Journal*, Ch. 811, was therefore launched, claiming "that the defendants might be restrained from laying down mains or works in the streets of Sheffield and from breaking up the roads, &c., or doing any other act whereby the passage of Her Majesty's subjects along the said streets should be in any respects obstructed or rendered less safe." This was the forefront of the attack; but the "relators" who had obtained authority to use the ATTORNEY GENERAL'S name, having paraded their public spirit, had a trifle of their own to urge, and therefore further asked that the defendants might be restrained "from doing anything whereby their (the legal) mains might be injured." An injunction having been refused by the VICE-CHANCELLOR, the case was fully argued before the LORD CHANCELLOR and two Lords Justices on Appeal. But, alas for orthodoxy, the attack failed, and the majority of the Court declined to condemn the heretics to extinction. The interference with public convenience was pronounced to be "of a transient nature, and at no one spot or to no one individual more than a passing and almost imaginary evil." This decision was followed by the Court of Appeal in a later case (Attorney General *v* Cambridge Consumers' Gas Company, L. R., Chap. 4, p. 71.) where the local parliamentary gas company were again the "relators." Here it was held that the disturbance of the pavement of a town (even though dignified with a university) by an unincorporated gas company, without lawful authority, for the purpose of laying gas-pipes was not a nuisance so serious and important that the Court would interfere by injunction; also that the views of the governing body of a town and the motives of the persons instituting the suit are not immaterial where the complaint is of a public injury.

In these cases it was not denied that the proceedings of the unparliamentary company were illegal, nor that they were liable to indictment before a criminal court if anyone thought it worth while to take such a step, nor that the company was liable to pay damages to anyone who could prove he had sustained any; but the Court did not consider this included prospective injury to another company's mains. The interlopers would also have to contend with other difficulties, such as have usually rendered a permanent existence under such conditions impracticable; and it is remarkable that the law reports record the fact that one of them was subsequently mulcted in damages in respect of an injury caused by servants of its contractor under circumstances where an authorised company would have escaped. What became of the competitors for the honour of illuminating the metropolis of cutlery and the seat of learning respectively, and which of them, following the usual law of development, ultimately swallowed up its rival we have never inquired; but it seems to us that the justice meted out to them now nearly half a century ago will do well enough for application to some cases we occasionally hear of at present in connection with electric lighting.

We believe the laying of electric mains in streets without Parliamentary powers is quite as illegal as the laying of gas mains, no matter whether the Local Authority consent or not. We also believe that the power of the Court to stop such proceedings by injunction still remains; but that it is ever likely to be exercised in any case where the local authority have acted *bonâ fide* in giving permission for such mains to be laid, we take leave to doubt. But after all, have electric lighting undertakers much to fear from schemes of this description? The risks and disadvantages attending any extensive operations by persons acting without statutory powers are such as must necessarily preclude operations except over a very limited area. A company formed upon such a footing must be standing on a most insecure basis. Assume that they have laid their mains with the goodwill of a friendly Local Board. The consent so given could hardly be expected to bind the Board and its successors for all time, so as to give a permanent charter to a company freed from the trammels of the Electric Lighting Acts. The benevolent vestrymen who once directed the counsels of the Board may cease to reign, and may be replaced by new rulers who know not the freehanded company, and abhor its works. Mains laid under streets are valuable so long as you can get at them for repairs and making new connections, but should all right of access be taken away their value would be a very uncertain quantity. Such action by a Local Authority would be less likely to happen, or if happening might not be a very serious matter where the work consists merely of a main crossing a single street, but the case would be very different if it involved mains extending the whole length of one or more streets. We think, therefore, it is unlikely that authorised undertakers will ever suffer seriously by competition arising from such a source. Not much progress could be made without the protection of a Provisional Order; and should this be applied for, we hardly think the Board of Trade would be impressed by the argument that a footing gained by illegal means constitutes a claim to favour, as against another party who has observed the requirements of the law. The plan of getting mains laid somehow, and then applying for a Provisional Order, may have answered a good purpose in some cases, and might serve again where there is an open field; but it is not likely to prove good tactics as a means of starting a regular competition with existing undertakers—at all events, where the latter are able and willing to supply the requirements of the district. Where these conditions are complied with, the Board of Trade do not favour competition, and we believe that any attempt to secure an advantage in such a manner would probably bring disaster upon the promoters of the scheme. With regard to the attitude of Local Authorities upon this question, we trust it will be one of fairness and moderation. The owner of large premises, and particularly a factory, may find it convenient and economical to generate his own current, and if he has some spare power it would not be unreasonable to allow him to employ it by laying a line across the road so as to light his opposite neighbour. But if he should convert his premises into an electric lighting station, and for the purpose, not of economy in his own business, but for carrying on war against an authorised electric lighting company whose behaviour has not given reasonable cause for complaint, he certainly ought not to have the countenance of the Local Authority. But even if the parochial rulers were so misguided as to support "unfair" competition, we should not, for reasons already stated, envy the illegal competitor his precarious tenure. Brief life would probably prove to be his portion.

REVIEWS.

Recettes de L'Electricien. By E. HOSPITALIER. (Paris: G. Masson.)

This eminently practical book comprises within its 350 pages a great variety of useful information. Commencing with the composition of fusible alloys, it concludes with a section on official documents or regulations relating to the use of steam boilers, electric plant, the laying down of underground mains, the use of electricity for lighting in theatres, &c., also instructions for the treatment of victims of electrical accidents, and a *résumé* of the patent laws of different countries, &c. An appendix gives the substance of a projected law relating to the erection of conductors for the transmission and distribution of electric energy, and a list of French customs duties on electrical materials and apparatus. An index and an alphabetical table of contents make the book easy of reference.

Among the receipts for alloys we notice solders for all purposes, including one to resist acids, and one which is said to adhere to glass, while a list is given of suitable alloys for fusible cut-outs with the melting points for each. On p. 215 we are told that copper is unsuitable for fuses, the reason given being that successive heating and cooling renders the metal brittle. It is within our knowledge, however, that tinned copper wire of the finer sizes is extensively used in this country with entirely satisfactory results. Among solders we notice one for aluminium which is said to be sufficiently malleable to bear hammering, turning and general working of the aluminium article after soldering; this is composed of 45 parts of tin and 10 of aluminium. Another harder solder for the new comer among our commercial metals consists of 52 parts of copper, 46 of zinc and 2 of tin; yet another, the components of which are to be melted together with borax, consists of zinc 70 parts, precipitated copper 15 parts, aluminium 45 parts.

Following chapters on bronzes, polishes and instructions for working in glass, we find practical instructions for making bobbins for electro-magnets. In the chapter on suspensions we find precise information for the making, fixing and attaching of quartz fibres, for which acknowledgment is made to Mr. Vernon Boys.

Passing to a chapter on dynamos we read: "It is frequently necessary to feel the bearings to ascertain that they are not heating dangerously." This is surely a relic of bygone days, when a dynamo was a piece of ill-constructed mechanism, and usually in charge of a fussy enthusiast who delighted in recounting his stupendous labours and the wonderful expedients he used to keep the lights going, or the pyrotechnic effect of spilling a box of tinned tacks into the rotating armature! In these days of large and well-proportioned bearings, sight feed lubricators, or self-oiling arrangements, and sparkless commutators, the amount of attention required by a dynamo of recent construction is as little as for any piece of apparatus running at the same speed.

For lubricating the commutator, M. Hospitalier recommends valvoline—a trace only—and this is a good lubricant for the purpose. We know of some engineers up North who put their faith in "commudine." According to them, the best treatment for the commutator of a modern dynamo is as follows:—Polish up the commutator with finest emery cloth, then apply "commudine" with a flannel until the surface is highly burnished. The brushes having been carefully bedded, the wearing surfaces should have a very small quantity of "grapholine" (a mixture of finest black lead with solidified oil or vaseline) spread upon them. The quantity of grapholine should not be sufficient to materially dim the lustre of the commutator.

The instructions *re* the construction of brush holders are generally good. We think something should have been said about the necessity for perfect bedding of brushes upon the commutator; also the very practical way of securing this—*i.e.*, the winding of a helix of emery tape over the surface of commutator, upon which the brushes are allowed to rest lightly until ground to the proper curvature—might have found a place among M. Hospitalier's very practical instructions.

With regard to carbon brushes, we believe that engineers in this country will endorse our view that even the lowest working density given in the book, *i.e.*, 7 to 8 amperes per square centimetre, is more than twice as much as it is advisable to take off with a carbon brush; even with 8 amperes per square centimetre the commutator gets to an uncomfortable temperature in a long continuous run. Having mentioned the use of emery tape for bedding metallic brushes, we may say that with carbon brushes all that is necessary is to insert a piece of emery tape or a strip of emery cloth between the commutator and brush. Let the brush rest on the emery surface with the usual tension, then pull the tape backwards and forwards a few times, making the direction of pull such that the tape lies on the curved surface of the commutator. The added thickness of the emery tape, of course, makes the curvature of the brush surface of slightly larger radius than it should be, but this is very trifling, and the result is far nearer perfect than can be obtained with a reasonable amount of labour by filing. The book should be found useful in the laboratory and test room.

Die Galvanoplastik. By JULIUS WEISS. Fourth Edition, revised, increased, and improved by JOSEF FRANZ BACHMANN. (Hartleben's Verlag: Vienna, Pest, Leipzig.)

Of the making of technical text-books there is no end, but they too often consist of a mass of ill-digested matter collected from previous works on the subject and from the technical press, and with little guidance supplied by the author to pilot the reader through the tangle of facts and fallacies. But occasionally we come across one of a different type, and such a one is "Die Galvanoplastik." The work is admittedly only a collection of information on the subjects of electro-plating and electro-typing which the author has made from current literature, supplemented by information supplied by firms, and by his own personal experience. So far, the book does not differ from many another compilation culled from technical literature; but there is this material difference: that, following the example of Dr. Langbein, Bachmann has stated which of the many processes he himself has tried. It is probably because so little attention is paid in this country to electro chemical industries that we have so few good works dealing with these subjects in our own language. But be this as it may, it seems a pity that electrical students should crowd into the electric lighting and traction industries to the neglect of all other branches of electrical work. Electro-plating had its industrial birth in this country, thanks to the foresight and enterprise of Messrs. Elkington, and for many years the problems involved in it occupied the attention of scientific men, with the result that the foundations of our knowledge of electro-chemical relationships were laid. With the advent, however, of a commercially useful dynamo, public interest was diverted to electric lighting and traction, while scientific workers turned their attention to the rich crops of interest and profit to be reaped in the electromagnetic field. The electro-plating and allied industries passed into the hands of the so-called practical man, and became stereotyped; but we hope that the great revival of interest in the scientific principles underlying these industries which has taken place in the last few years will result in a better state of things again prevailing.

"Die Galvanoplastik" is, nominally, the fourth edition of the well-known work by Julius Weiss, but may be practically considered as a new book, as it has been thoroughly rearranged and brought up to date by J. F. Bachmann, to whom the revision of the work was entrusted on the death of Weiss. The book is divided into four parts—the first dealing with physical and electro-chemical laws; the second with the practice of electro-plating and colouring, which latter includes the production of deposits of various hues by a suitable preparation of the bath (as in the case of gilding), or the production of the so-called "interference colours," which are caused by the deposition of very thin metallic films. The third part deals with electro-typing, and very full directions are given for the various processes involved in the reproduction of medals, coins, busts and plants, and the copying of engravings and photographs, &c.; whilst the fourth part is devoted to the chemicals and materials used in electro-plating, and some estimates are given of the plant required for different pur-

Digitized by Google

poses and its approximate cost. In the introduction is given, in chronological order, the fullest list we remember to have seen of the workers in the field of electro-chemistry, with a brief statement of the most important advance in our knowledge of the subject for which we are indebted to each. The names of the most prominent workers at present employed in this branch of theoretical and applied science are also enumerated, which will be of advantage to the student.

In dealing with the science of electricity, and with the apparatus and means employed for generating, regulating and measuring the electric current, the author has confined himself to a statement of those facts which are of importance to the working electro-plater; but very full references are given to the literature of the subject, so that the reader can obtain further information on all points should he desire it. The space gained by this condensation is employed for a very thorough treatment of the electrical and chemical relationships on which all the electro-chemical processes rest. The aim has been to produce a work which, while scientifically accurate, shall be useful to the practical man, who too often has had small opportunity for mastering the scientific principles underlying his work, and for this reason the preparation of the baths is given in popular language and at some length. In describing the various processes one or two selected baths which the author has tested are given first, and then those which have been recommended by workers of repute, and which have been found reliable. The beginner is thus enabled to make a bath which will give fairly good results, while the experienced hand has a selection of recipes from which to choose one which is particularly adapted to his purpose.

The deposition of nickel is very exhaustively described, not only on account of the great importance to which the industry has attained in the last 15 years, but because the precautions to be observed in it are applicable to all electrolytic processes; therefore this chapter may be taken as a type of the whole book. Great stress is laid on the necessity of absolute cleanliness, for, as is pointed out, the careful worker will get good results from baths which are not theoretically the best, while the most scientifically-prepared solutions will only yield inferior work in careless hands. The author's remarks, too, on the subject of manufacturers who set up works, and are dependent on their workmen for the preparation of the baths, and on the workmen who undertake duties which they do not understand, will find an echo in this country, for we fear it is not in Germany alone that men are to be found seeking employment as electroplaters whose sole experience has been that of removing grease from the articles to be plated, and suspending them in the baths, and who are absolutely ignorant of the electro-plating process itself.

Electrical Engineering as a Profession: How to Enter it, and Guide to the Engineering Profession. By A. D. Southam, A.I.E.E. (London: Southam and Co.)

A careful perusal of the latest edition of Mr. Southam's *brochure* does not reveal to us any reason for altering the opinion we formed of it about a year ago. It professes to be a guide; it is nothing of the kind. Placed before an anxious parent it would be as helpful to him as an ordnance map in the hands of a yokel who had missed his way in a strange county. To those who want to have in a handy form information as to the fees and curricula, the aims and objects of some of our leading technical colleges and cognate institutions, Mr. Southam's compilation will undoubtedly prove useful. What manner of "guide," however, to a parent or guardian is a mass of contradictory opinions of engineering experts as to the best mode of entering the profession. What help to a proud father are details such as the following:—"Generally speaking, the instruments are upstairs. Among others may be mentioned a Thomson hecto-ampere balance, and a standard balance for one ampere. . . ." What advantage is it to him to know that the engine room in the basement is connected to the laboratory upstairs by "three pairs of leads and pneumatic tubes." If the author has an opinion as to the best way of becoming an electrical engineer, let him give his readers the benefit of it shortly, sharply and to the point, and if the parent must gauge for himself in a hazy way the relative merits and demerits of various institutions, he would be better assisted by a comprehensive table than by the numerous illustrations and the, to him, unintelligible details at present given. The author should also make it clear that some of the institutions he describes are purely private concerns, undertaken for purposes of personal profit, whilst others are more or less public and philanthropic. Even so the parent or guardian would probably be exceedingly puzzled by the fact that you can procure for a few shillings north of the Tweed, what costs a few hundred pounds just north of the Thames. Some idea should certainly be given of the social status of the students and the amount and mode of endowment of the various colleges. Another point upon which reliable information is invariably required by those about to settle their sons in life is the probability, given average abilities, influence and luck, of a decent livelihood being obtained in any particular profession. A parent does not need to be told that "much depends on the general ability of the intending pupil and the earnestness which he applies to his future career"; common sense will tell him that. Nor does the additional information that "there is always room for a good man and one who knows his business" mend matters much. What the purchaser of a "guide" has a right to expect in return for the purchase money is some clue as to the relative chances of success in different professions or in different branches of the same profession. It is admittedly a difficult matter to gauge, but it is not an altogether insoluble problem. For instance, no one would recommend telephony in England as affording much chance of a brilliant career to an eager young fellow with a *penchant* for scientific research work.

Mr. Southam's book cannot fairly be called a guide until it contains less undigested information and more plain advice. As a catalogue of engineering colleges and firms it will pass.

The Engineer's Year Book. 1896. By H. R. Kempe, A.M.Inst.C.E. (London: Crosby, Lockwood and Son.)

We are glad this compilation is not called a pocket-book, since a load of 18oz., occupying a space 7in. × 4¾in. × 1½in. is not suitable for the average pocket. At the same time the term year-book, notwithstanding the fact that the work is issued annually, seems also somewhat of a misnomer, since it implies that the information contained is such as requires annual revision; but as by far the greater number of the 634 pages are devoted to formulæ, tables, and constants, it is not easy to see where the necessity for annual republication comes in. The electrical section of the Year Book is distinctly inferior to the rest of the work. Memoranda likely to be of real use to an electrical engineer when away from his own note-books and works of reference, are conspicuous by their absence, and their place is taken up by manufacturers' lists and execrable and unintelligible illustrations of motor-car trucks, the whole being profusely and irritatingly interleaved with advertisements. On p. 508, by a slip of the pen, no doubt, we are told that electricity is more economically transmitted at a low than at a high potential. We trust advantage will be taken of the yearly publication of this volume to thoroughly reorganise this section at an early date.

Hazell's Annual for 1896. Edited by W. Palmer. Eleventh Edition. (London: Hazell, Watson and Viney.)

The great merit of this book of reference is that the contained data is all arranged alphabetically so that when looking up a reference in a hurry, as one always does, there is little danger of loss of temper and time in a wild fruitless hunt after a particular item of information; it is almost as easy to find what one wants in this Annual as it is to find a word in a dictionary. As to the value of the information when found it varies considerably. The section on engineering, for instance, which contains brief descriptions of the chief industrial engineering enterprises in progress throughout the world, is excellent, as is also the section on factory and workshop legislation. On the other hand the paragraph devoted to the inventions of 1895 is decidedly poor; it opens with the "Octopus" anti-incrustator, and concludes with an account of the horseless carriage show at Tunbridge Wells. The section on electricity is, quite rightly, mainly occupied with the opening of the Niagara Falls power-house and the develop-

Digitized by Google

ment of electric traction, but these two items should not have been permitted to practically exclude everything else. However, taking it for all in all, it is a handy book of reference.

Griffin's Electrical Engineer's Price Book. Edited by H. J. Dowsing. New edition, revised throughout, and enlarged. (London: Charles Griffin and Co.)

The 1896 edition of this useful work is radically different in shape and general get up to the first edition published in the summer of 1893. Part I. consists of a well-arranged collection of the price lists of a large number of makers. Part II. comprises central table statistics, specimen reports, &c. To those who do not happen to keep a file of manufacturers' catalogues, or who wish to have the same information in a more portable shape, Mr. Dowsing's compilation should prove a decided boon.

Lockwood's Price Book. 1896. Edited by Francis T. W. Miller (London: Crosby, Lockwood and Son.)

A little over 20 pages of small type are allotted this year to the prices of electrical plant and accessories, exclusive of bells and batteries, which occupy another six pages. The information given is varied, accurate and useful.

Laxton's Price Book. 1896. (London: Kelly and Co., Limited.)

The 1896 edition of this work comprises 750 pages, some 80 of which are allotted to electric lighting. Although the editor informs his readers in the preface that "the important section of Electric Lighting has received special care and attention," there is no observable improvement. As in previous years this section is almost entirely given up to the price lists of two firms; it contains a good deal of ancient history, and no mention whatever is made of *the* high-speed electric lighting engine.

HIGH-VOLTAGE LAMPS, AND THEIR INFLUENCE ON CENTRAL STATION PRACTICE.*

BY G. L. ADDENBROOKE.

In the spring of 1891, which was the last occasion when the Alternating *v.* Continuous-Current controversy came prominently before this Institution, and when Mr. Crompton brought forward his feeder argument, I had the honour of opening the discussion, and subsequently continued the argument in the technical Press, besides going into it privately with Mr. Crompton. I was not, however, convinced of the superiority of *low-pressure* direct supply, and on the old premises I remain unconvinced still; but I saw that the advantages of the two systems were in many cases very nearly balanced, and if one or other was ultimately to prevail it would probably be for some other reason than lay in the arguments which had so far been brought prominently forward on either side. It was, in my mind, useless to say that the two systems were each the best for certain situations; for how was the line to be drawn? or, in some cases, were we to have both systems in one town? Though a possible, this did not seem to me a desirable solution.

The question is not merely an academic one; hundreds of thousands of pounds are every year now spent on electric lighting, and that a large portion of this sum should be spent in a way that is not the best and most permanent is a serious matter. Besides this, as a consulting engineer, I found my position an unpleasant one. What was I to recommend to my clients? and if I halted between two opinions, what would my clients think of me? I regret that in these matters I have not the assurance of some gentlemen who, I understand, circularise all town councils, keep their own touts, and are prepared to give cut-and-dried verdicts without hesitation on engineering points which, I must confess, I approach with a certain amount of awe and misgiving, and a very serious sense of responsibility.

Now, it struck me four years ago, as I daresay it did others, that, as the two methods had been argued over so carefully without any definite conclusion being arrived at, probably some outside and fortuitous circumstance which neither side had taken account of would ultimately turn the balance one way or the other.

Possible Sources of Influence on Central Station Practice.

I therefore made a careful survey of the field, and the only eventualities I could think of, or which seemed likely to have a very important bearing on the problem, were the following, viz: the introduction of (1) an altogether new form of lamp; (2) a cheaper material for mains than copper; (3) a high-voltage incandescent lamp; (4) a much more economical incandescent lamp of the present voltage; (5) an improved and much cheaper storage battery.

Respecting a new form of lamp: After having seen Tesla's experiments at the Royal Institution, and after having learnt privately the views of some of our leading investigators on the field which they opened, I must say, as a practical man, I did not see any immediate hope of commercial success in this direction, however interesting the results might be scientifically. As regards the chance of a cheaper conductor being forthcoming, I have dealt with this question at length in a recent article in the *Electrical Review*. Owing to the cheap rate at which aluminium can be produced, and will increasingly be produced in the future, and since the conductivity of aluminium is 56 per cent. that of pure copper of the same section, the chances of aluminium ultimately supplanting copper are strong, but the change will undoubtedly be a comparatively slow one. The possibility of this, however, points to a reduction in the price of conductors; and this, of course, would tell somewhat in favour of moderate pressures. Again, as even in moderate-pressure mains insulated with bitumen or other compounds the cost of insulating is twice the cost of the conductor itself, in the sizes usually employed, it is quite conceivable that very important economies may be effected in this direction. It is obvious that improvements of this character would probably tell more in favour of moderate pressure than of high.

Having thus disposed of the conductor question we come to the third and fourth alternatives I have mentioned as likely to influence central station practice, viz, the introduction of a lamp of higher voltage, or a more economical lamp of the present current-voltage. When thinking over the matter in 1891, I saw that, as fairly good lamps of 8 c.p. for 100-volt and 110-volt circuits were being made, two of them could be put in series, and that we should get very simply a 16 c.p. lamp of 200 to 220 volts. This, however, involved giving up 8 c.p. lamps except two in series, which, as the charge for current was then usually 8d. per unit, was a serious matter, and again, as there were two filaments in each lamp, the breaking of either of which would spoil the lamp, this also introduced an important objection, particularly as the Ediswan monopoly maintained the price of lamps at 3s. 6d. for ordinary voltages, and could hardly be expected to supply lamps which would be more expensive to make, except at an enhanced price. The prospect of obtaining high-voltage lamps, did not, therefore, at that time appear bright. Time has, however, brought about great changes in the lamp industry, due largely to the expiry of patents, which quickly led to numbers of good lamps being placed on the market at less than one-third the price formerly charged, and at the same time brought active and pushing competitors into the field.

Two years and a half ago, finding some disposition abroad to adopt higher voltages, I drafted an article pointing out the enormous gain which would accrue in the distributing system if higher voltage lamps were adopted, intending to send it to one of the journals. The question, however, then appeared somewhat problematical, and other business led to the article being put on one side. I did not, however, forget the matter, and last December year, finding that one or two firms were trying to introduce lamps of 200 volts, I looked over my draft again, and having somewhat elaborated it, sent it to the *Electrical Review*. The article attracted the attention of Mr. Baynes, then of Bradford, and he wrote detailing his experience, and the experiments he had made with high voltage. Since then the matter has advanced by leaps and bounds. Several lamp makers are undertaking to supply 16 c.p. lamps of voltages up to 230 and even above; and not only this, but Mr. Stearn and one or two other makers are offering lamps up to this voltage of 8 c.p. also, and guaranteeing a fair economy. The lamps are also being offered at moderate prices.

Low-tension central station engineers have not been slow to perceive the facilities these lamps offer. In some cases they have been adopted publicly, and in other cases private experiments are being made on them with satisfactory results. I also hear from those manufacturers who are catering for the market that the demand for high-voltage lamps is steadily and rapidly increasing. The adoption of these lamps is, of course, somewhat in the tentative stage; but so much progress has been made, and the results attained so far are so good, that no one can doubt that in a year or two they will become a permanent institution. It may also be noted here that since this paper was sent in I see that Prof. Kennedy has considered the 230-volt lamp sufficiently sound to recommend the Town Council of Edinburgh to adopt it.

Concurrently with this development there has been a tendency towards the use of lamps of ordinary voltage but of higher efficiency, and I must say that until recently I have been unable to quite make up my mind which was the best of the two lines to work on—whether it would be better to use lamps of 100 voltage and taking $2\frac{1}{2}$ watts per candle-power, or lamps taking 4 watts per candle-power with a voltage of 200 or 220. I think, however, the matter

* Paper read before the Institution of Electrical Engineers, February 27, 1896.

Digitized by Google

now admits of being argued out pretty clearly. By a reduction of current per candle-power in the proportion of 2½ to 4, mains of a given capacity would do nearly double the amount of lighting with the same expenditure of energy. Energy in itself is very cheap, however, and any fair-sized central station could supply double the quantity of energy it is now doing at 1½d. per unit for the extra current, if this did not entail extra expense for mains. Now, by doubling the voltage, we reduce the size of the mains to one-fourth, other things being equal; consequently the mains for a station using 220-volt lamps consuming 64 to 70 watts per 16 c.p. lamp, to give the same percentage loss, would not be much more than half the size they would be if the station supplied 110-volt lamps consuming 2½ watts per candle-power, as the current would be nearly the same in both cases. As the cost of mains is such a very large proportion of the whole central station cost, and as energy can be generated so cheaply, I am fairly confident that, even if a good 2½-watt lamp were obtainable, it would pay better to use 220-volt lamps taking nearly double the current.

Conversations with lamp makers, and recent publications on the subject, have convinced me that a good 2½-watt lamp of 100 volts has yet to be attained, and will probably be a very difficult thing to achieve, unless absolutely even pressures in the mains can be guaranteed. The opinion of lamp makers appears universally to be that a 220-volt lamp at 3½ to 4 watts per candle-power is a more practicable and attainable object than a 100-volt lamp at 2½ watts. They seem also unanimous that if a good 2½-watt 100-volt lamp could be made, a good lamp of 220 volts, and of better efficiency than 4 watts, would be forthcoming. It therefore appears that by taking a 220-volt lamp now we shall get all the advantages of high voltage, and in time shall get nearly as efficient a lamp as if a lower voltage were used, while the high-efficiency lamp is even now in a far less forward state of development than the high-voltage lamp. Consequently, it seems clear that the high-voltage lamp is the better line of the two at present.

Besides this, we are anxious to cheapen the cost of current so that it may also be available for power purposes, and thus small economies in consumption will be of less and less moment. It is, therefore, obvious that not only in the present, but for the future, the high-voltage lamp is likely to be the better, and that it is safe to run the risk of being unable to use very economical lamps, provided decent ones of high voltage can be obtained.

I shall not pursue this branch of my subject further, as it would be more suitably dealt with by a lamp manufacturer in a special paper; but I think enough has been said, coupled with the knowledge members already have of the subject, to show that high-voltage lamps are thoroughly practical for central station work, and I therefore pass on to consider how far it is desirable to use them, and what effects they are likely to have on central station practice; this being more immediately the subject of my paper.

Life of High-voltage Lamps.

We can, of course, hardly expect the life of these high-voltage lamps to be as long as that of lamps of half the voltage, while at the same time they will be rather more expensive, consequently there will be a greater expenditure for lamp renewals when they are used; and it is advisable, I think, to try and arrive at a figure for this before proceeding further.

If the life of an ordinary 16-c.p. lamp of 100 volts is 1,200 hours, and it consumes 64 watts, during its life it will consume 77 B.T. units, which, at 6d. per unit, amounts to 38s. 6d. If the cost of the lamp is 1s. 3d., its cost per unit of current consumed is 0·2d., or ⅕d., or about 3 per cent. of the cost of the current. For an 8-candle lamp of 100 volts, lasting 800 hours and taking 36 watts, the consumption of current is 29 units; and at the same price for lamps, the lamp cost per unit of current consumed is about 0·5d., or ½d., or about 8 per cent. of the cost of the current. I have assumed the above life for these lamps because I think, after burning the number of hours indicated above, most lamps would be best thrown away; though I am perfectly aware lamps often last twice as long as I have assumed, and they can also be purchased for 20 per cent. less from reliable makers. 200- or 220-volt lamps will, of course, cost rather more, and their life would be rather less, but I believe I am putting the case more adversely for the higher-voltage lamps than is really true, in taking the cost as double the above rates for lamp renewals where high-voltage lamps are used. The cost of lamp renewals would then be 6 per cent. of a customer's bill if the current was 6d. per unit for 16-c.p. lamps, and 16 per cent. if 8-c.p. lamps were used. Supposing the number of 16 c.p. lamps installed to 8-candle lamps is about as 1 : 2—which is, I think, about a fair average—an all-round reduction of 6 per cent. in the charge per unit of current would cover the *additional* cost of lamps if lamps of high voltage were used; at 6d. per unit for current this is about one-third of a penny per B.T. unit.

Such figures as these can only be approximate, but I think you will agree that they would not be far out in practice, and may be improved upon, and also that they make it clearly manifest that the extra cost of using high-voltage lamps offers no appreciable bar to their introduction, providing that their other countervailing advantages are in excess, with which branch of the subject I will now deal.

Effect of using High-voltage Lamps on Distribution.

On this point I do not think I can do better, as a commencement, than quote from my article in the *Electrical Review* of the 11th of January, 1895:—"How great a gain there is in distributing current at a higher voltage, and how much it simplifies the distributing problem, is not at first sight fully apparent, though everyone recognises that there are advantages. The advantages may really be said to progress as the cube of the voltage, up to, say, about 200 volts. For let us suppose we have a station on all of whose circuits the lamps require 200 volts to incandesce them, instead of the usual 100 volts. In the first place, having doubled the pressure, we may extend our mains double the distance at the same current-density, with the same percentage loss; but at the higher voltage the same current-density in a given sized main will give us twice the energy and light twice the number of lamps. Consequently, without increasing the sectional area of the mains, we can do four times the lighting with the same mains, or the same amount of lighting at four times the distance with the same percentage loss. Then there is a further gain, for, since we can extend the mains four times as far from the central station with the same percentage loss, the area which can be served from a single station is 16 times greater at the higher pressure than at the lower. Presuming, however, that this argument is not pushed to its extreme limits, it is well within the mark to say that at 200 volts nine or ten times the area could be better served on the three-wire system from a single station than is now the case at 100 volts; not only is this the case with the feeders, but it extends in an even greater degree to the distributing system. At present there is no doubt that there is an inconvenient fall of voltage in the distributing mains, and the internal wiring of houses, which leads to irregular and unsatisfactory lighting, and which is under existing circumstances, whatever system is employed, exceedingly difficult to remedy. If by any means the voltage could be increased to 200 volts this would practically vanish, distributing mains might be carried three times their present distance from the feeding point, and the fall of potential in houses would be merely nominal on the present basis of wiring, instead of frequently amounting to 1-2 volts or more. By these means the number of feeding points in a given area would of course be much reduced. The same fittings and wiring as are now used would be applicable, and the voltage does not go beyond the Board of Trade limits."

This was a general statement, made largely with a view to point out to manufacturers what a field it would open if they could produce a commercially satisfactory high-voltage lamp. During the last eighteen months manufacturers have seen the advantage of exploiting this field, with results which have already been detailed above. Consequently it is desirable to look a little more closely at the distribution problem under its new aspect, and I will, therefore, ask your particular attention to the figures which I now propose to lay before you.

It is generally acknowledged that in the three-wire system at 110 volts it is not economical or very practical to distribute current at a radius of much more than three-quarters of a mile from the central station, except under special circumstances. The area which can therefore be economically served from such a station is about one and a-half miles each way, or about two and a-quarter square miles. In his well-known feeder paper Mr. Crompton gave figures which he argued showed that a feeder on the three-wire system supplying 110-volt lamps could be laid and maintained, and would involve the same loss of energy, taken over the same day, as would an alternating feeder, including transformers, instruments, and switching gear, the length of the feeders in each case being 2,400 yards. These figures were strongly attacked by the alternating party, myself amongst the number; the most legitimate point of attack being that Mr. Crompton had assumed a loss of 30 per cent. at full load on the low-pressure feeder, which was considered excessive on account of the extra plant it would entail at the central station. Had Mr. Crompton put the length of his feeder at about 1,400 yards, or a little over three-quarters of a mile, and had he used a density of about 500 amperes per square inch—which is about the practical density—the loss would have been 16 per cent. for the continuous-current feeder at full load, and few alternating men would have seriously combatted that on the whole the continuous-current feeder was as economical and desirable as an alternating feeder. The figures would then agree with the generally current comparison which I have mentioned above, and which I propose to use as a basis of argument in order to avoid disputes.

Now, from data I have collected, it appears that in such places as the centre of large towns there are perhaps 30,000 inhabitants per square mile, though ordinarily the population for a square mile of a town does not appear to exceed 16,000. A low-pressure station on the three-wire system with 110-volt lamps can therefore serve economically about 60,000 to 70,000 people in the centres of large

Digitized by Google

towns, and about 35,000 in districts outside the centres and in provincial towns. If, therefore, we wished to light London, with its 4,000,000 population, on this basis, taking the average population at 25,000 per square mile, we should need, roughly, 70 to 80 stations to light the whole metropolis, not counting the extreme suburbs.

If, however, in the direct supply system the voltage is double, the position is altogether altered, and a comparison between the transformer and direct supply systems under these circumstances will lead to very different results from those so far given. Theoretically, if 220-volt lamps are used, we can extend the feeders four times as far as if 110-volt lamps are employed, and therefore the area which could be lighted from each station is 16 times as large. I do not intend to take full advantage of this facility in the calculations which I propose to lay before you, as I consider that the fall of voltage is too large in low-pressure central stations at present, and that the voltage of the lamps at different points of the distributing system is not kept as near the normal as it should be. In what I am about to say I shall therefore consider that, instead of four times, we extend our feeders a little over three times as far as before, thus securing better regulation and a smaller percentage drop in both the feeders and distributing system, together with the great saving in copper. If, then, we can extend the lighting radius three-quarters of a mile from a low-pressure direct supply station with 110-volt lamps, we can extend it, on the above basis, 2¼ miles at 220 volts, which means that we can cover an area of 5 × 5, or nearly 25 square miles from one station—that is, 11 times the area we could before. Instead, therefore, of serving 60,000 people in the central districts, one central station would serve 700,000, and over a quarter of a million in the less central districts. Taking, then, the population of London as 4,000,000, without extreme suburbs, about six or seven stations would comfortably cover the whole area. Now this is a number which is directly comparable with the number of stations at present being operated by the gas companies; and to my mind it is doubtful if it would be desirable to reduce the number of stations below this figure for so large an area, even if it could be managed.

It would be interesting to go into this metropolitan lighting problem further did time permit, but it does not, and I must ask you now to turn your attention to the provinces. Take maps of Birmingham, Liverpool, Glasgow and Manchester, and cut out a piece of tracing paper to represent 25 square miles on the same scale as the map. Lay the tracing paper over these maps, and you will find that two stations, or at most three, will cover not only the whole of these great cities, but the suburbs for a couple of miles outside. For the general run of large towns one station would amply suffice; and for the smaller ones one station would, of course, permit of lighting over the whole area at a very small expense for mains. Before a technical audience like this, however, it will doubtless be more satisfactory to investigate a particular instance than to proceed further with general statements.

At 220 volts pressure an ampere represents 220 watts; therefore, one-third ampere represents 73·3 watts. Now at 4 watts per candle-power a 16-c.p. lamp takes 16 × 4 = 64 watts, and an 8-c.p. lamp 32 watts. We shall therefore be sufficiently near for the purposes of this calculation, and shall be allowing a sufficient margin, if we assume that a 16-candle lamp takes one-third ampere, and an 8-candle lamp one-sixth ampere at 220 volts.

Next consider the distributive system. There are two points needing attention: the first is, How far, and over what area, can we spread our network from the feeder points? The second is, What drop should we allow on the feeders themselves?

But before going into these matters further we must settle what shall be our greatest drop from the feeder point to our furthest lamp on the network spreading from it. The variations which are permitted at present are too great, and would have to be reduced in time anyhow. I therefore do not intend to adopt the present practice as a basis, but to take as the limit an extreme fall of 2 per cent. on the distributing system from the feeder point to the furthest lamp at the tops of the houses; that is, lamps near the feeder would be 1 per cent. above their proper voltage at full load, and extreme lamps 1 per cent. below. This is, I think, as large a variation as good practice would allow, though it is less than half what is considered permissible now. Having settled this, the following data and table will enable us to see at a glance the best method of designing the mains and their cost.

1. A bar of copper 1in. in section and 1 mile long weighs approximately 9 tons, and its resistance is $\frac{1}{2}$nd of an ohm, or 0·045.

2. Therefore a double conductor 1 mile long and 1in. in section weighs 18 tons, and its resistance is $\frac{1}{11}$th of an ohm, or 0·090.

3. I do not think it will be necessary on the high-voltage system to have the third wire in a three-wire system more than one-fifth the section of the other two, except, perhaps, in the distributing system. In fact, I understand Mr. Crompton considers the third wire could be done away with altogether as soon as the feeder gets a good load joined up to it, so that only the distributing system would need the third wire, these wires being joined together at the distributing point.

Consequently, the weight of a set of mains on the three-wire system—the two outers 1in. section, and the inner one-fifth of an inch—would be 20 tons per mile; and the cost for copper at 6½d. per pound, would be £1,210 for the copper in the mile of mains. Now at 1,000 amperes per square inch a main this size would carry current for 6,000 16-c.p. lamps, if perfectly balanced on the above basis, and the fall of pressure would be 90 volts in the mile, or 17 per cent. Such a fall of potential as 17 per cent. in the mile is excessive, and therefore we must arrange to work at a smaller current-density.

To enable the best current-density to be judged I have arranged the following table:—

Data Relating to Feeders on Three-wire System Supplying 220-volt Lamps—$\frac{1}{3}$ Ampere per 16-c.p. and $\frac{1}{6}$ Ampere per 8-c.p. Lamp.

Current-density in amperes per square inch.	Loss in volts per mile of double conductor.	Percentage fall of potential at full load.	Kilowatts available per square inch section of outers = 2·2 sq. in. copper.	Number of lamps carried by mains 1 sq. in. section = 2·2 sq. in. copper.		Cost per mile of copper at 6½d. per pound.			
						Per lamp alight at once.		Per lamp installed = twice lamps alight.	
				16 c.p.	8 c.p.	16 c.p.	8 c.p.	16 c.p.	8 c.p.
		Per cent.				s. d.	s. d.	s. d.	s. d.
1,000	90·0	17·0	440	6,000	12,000	4 0	2 0	2 0	1 0
500	45·0	9·3	220	3,000	6,000	8 0	4 0	4 0	2 0
400	36·0	7·6	176	2,400	4,800	10 0	5 0	5 0	2 6
300	27·0	5·8	132	1,800	3,600	13 5	6 8	6 8	3 4
250	22·5	4·86	110	1,500	3,000	16 0	8 0	8 0	4 0
200	18·0	3·85	88	1,200	2,400	20 0	10 0	10 0	5 0

This table enables us to see the reduction in fall of potential which we get by reducing the current for a given section, and also the cost for copper which will be incurred for such density per mile run.

Now it is not unusual in some low-pressure central stations to have falls of even more than 16 per cent. at full load on the longest feeder; but this is an undesirably great fall, save on exceptional occasions, such as Christmas week, or during a fog in winter, and I think, with the immense reduction in copper cost which the use of high-voltage lamps gives, it is desirable to work with smaller falls. Suppose we accept 250 amperes per square inch as a basis, it will be seen that mains on the three-wire system will cost us 16s. per 16-c.p. lamp alight at once, and 8s. per 8-c.p. lamp per mile, and the drop of potential will nearly be 5 per cent. Now, if we assume that current is supplied 2½ miles from the station as an extreme, as we did before, our longest feeders will be about this length, the drop at full load on the feeder will be about 12 per cent., and the cost of copper 40s. per 16-c.p. lamp, and 20s. per 8-c.p. lamp alight at once for the longest feeder.

If we take the network as proceeding from the feeder points at the same current-density—namely, 250 amperes per square inch—and if we agree that it shall extend rather over a quarter of a mile from the feeder point, to allow for irregularities, so that each feeder will feed a network covering half a mile square, it will be noted that the drop, including extra lengths of main for going round angles and into the houses, will be about 1½ per cent., and the extreme cost of copper per lamp alight at one time in the network will hardly be more than 4s. per 16-c.p. lamp, and 2s. for an 8-c.p. lamp, while the mean cost will be about three-fourths of this, and the mean drop of potential only 1 per cent.,—and even this can readily be reduced by a little judicious adjustment.

We therefore see that for feeders extending about 2¼ miles, and a network extending a quarter of a mile further from the feeding point—that is, 2½ miles altogether—the extreme cost for copper per 16-c.p. lamp lighted at once will be about 44s., and for an 8-c.p. lamp under 22s.

This represents extreme lengths. The average length of feeders to cover the above area would hardly be more than 1¾ miles, or three-fourths of the above maxima, and the cost of the copper, on the average, in the distributing system will be reduced in like proportion. We shall therefore be correct in taking three-fourths of the above sums as the average cost of copper per lamp lighted at once from station to lamp, including both feeder and network, in a station covering a town area of equal density 25 sq. miles in area. This is, approximately: Per 16-c.p. lamp, 33s.; per 8-c.p. lamp, 16s. 6d. Further, from practice and the tables in *Lightning*, we know that there are usually at least twice as many lamps installed as are required alight at once; therefore we may put the capital cost of mains for copper only at about: Per lamp installed—cost of copper, 16 c.p., 16s. 6d.; 8 c.p., 8s. 3d.

Now it is fair to take 6 per cent. per annum as the sum to allow for interest and depreciation on the copper in the mains—say 3½ per cent. for interest, and 2½ per cent. for depreciation. At this rate, on the above capital cost, the annual cost for interest and

Digitized by Google

upkeep comes out at under 1s. per 16-c.p. lamp, and 6d. per 8-c.p. lamp installed.

Further, on looking through the tables of consumption of current, it will be found that 18 units per 8-candle lamp installed is a fair all-round average—at least, it is the average from *Lightning* for London and most of the provincial stations. At this rate, therefore, it will be seen that the upkeep and interest on capital for the copper in the distributing system comes to 0·33d., or one-third of a penny per unit of current sold; or, supposing the sum actually received for current is 6d. per unit, the cost for interest and upkeep on the copper in the distributing system represents less than 6 per cent. of the cost of current. Out of this cost, it will be noticed that about three-fourths of the copper is in the feeders, and one-fourth in the distributing system.

I may say that Mr. Crompton objects to the method of taking the consumption per 8-c.p. lamp installed as a basis of comparison, and I quite agree that it is rough and unscientific; and it might be well if our friend the editor of *Lightning* would look into it, and see if he could not get a sounder basis for comparison. Mr. Crompton suggests the relation between the annual output in B.T. units, and the output which would be registered if the maximum load were continued day and night throughout the year. In this case he tells me the actual output would vary from the equivalent of full load for 700 hours in some country towns to 1,000 in parts of London, 1,300 in Kensington, and a much higher figure for the Pall Mall and St. James's Company. 1,300 hours corresponds to a load-factor of 15 per cent.; though it will readily be seen that it is a figure of more comprehensive nature, and not exactly similar. I leave this question here, however, as, though very interesting, to discuss it further now would be out of place in this paper. In order to complete the comparison made above, the cost of insulating and of laying the cables should, of course, be taken into consideration. In order to set this point at rest, Mr. T. O. Callender has kindly prepared for me data deduced from their experience in supplying and laying cables, which, as a result of a large amount of practice, are beyond cavil, and which show the average cost of cables laid as compared with the cost of the copper in them. These particulars are given in the following table:—

Table showing the Total Cost of Insulated Cables laid complete, as compared with the Cost of the Copper Contained.

Character of cables (separate.)	Amoured, laid direct.	Plain, laid in solid bitumen.	Armoured, laid direct.	Plain, laid in solid bitumen.
Area of Cable { Outer	Sq. inch. 0·50	Sq. inch. 0·50	Sq. inch. 1·00	Sq. inch. 1·00
Area of Cable { Middle	0·25	0·25	0·50	0·50
Area of Cable { Outer	0·50	0·50	1·00	1·00
Cost of cable laid complete, exclusive of excation	19s. per yd. £1,650 per mile.	25s. per yd. £2,200 per mile.	33s. per yd. £2,900 per mile.	42s. per yd. £3,700 per mile.
Excavation, cheap streets and lanes	s. d. 1 3	s. d. 1 3	s. d. 1 3	s. d. 1 3
Excavation per yard, average run of trench in towns under macadam or pavement	2 0	2 0	2 0	2 0
Ratio of cost of copper (at 7d. per lb.) to cost of complete cable laid, as 1	2·5	3·1	2·2	2·3

Under asphalte or wood the cost of excavation will run up to as much as 15s. per yard run, but this item will practically be the same whatever system is used. Moreover, as only a few of the main streets in large towns are so paved, this item is not one which need concern us particularly in a general comparison, but must be dealt with in accordance with local circumstances in each case. It will be noticed that in the above table the middle wire is half the section of the outers; in practice it would not be necessary to have this more than one-fifth for the feeders, and in some cases it might be omitted entirely. The actual cost of feeders should therefore come out about 10 per cent. under the prices given, though I have thought better to leave the table as it was, preserving Mr. Callenders's own figures.

At these rates, for a two-mile feeder of armoured cable, working at a current-density of 250 amperes per square inch, the cost, laid complete, would be about £55 per kilowatt for the maximum output; the fall of pressure being about 10 per cent. I think, therefore, [that the whole distributing system—consisting of feeders, branches, local services, service boxes, and every other item, also providing for a fair proportion of the cables being laid under asphalte or wood, from such a station as I have described above, with a service extending 2½ miles in all directions—could be laid complete for £60 per kilowatt.

This is a very moderate figure as compared with the sums now spent. If we assume that 8 per cent. is required to meet interest, upkeep, and depreciation on this outlay, and if we take the output of the station at 800 kilowatt-hours maximum load on the basis suggested by Mr. Crompton, it is evident that interest and upkeep on the distributing system would cost about 1½d. per unit of current sold for the whole distributing system; so that a charge of 1½d. per unit would cover all costs outside the station itself. From what we know of the cost of generating electric energy, it will, I think, thus be clear that, even in places where coal was expensive, a very good profit would be made by selling current at 4d. per unit for lighting, and 2½d. for power purposes. In making this calculation I have assumed the same density of population over the whole area; but it is evident that this would very seldom be the case, as in nearly all towns at two miles from the centre the density of population is greatly reduced, which would mean a smaller proportion of long feeders, and consequently a less average cost per kilowatt output than I have taken

I do not wish it to be assumed from what I have said above that the capital cost of a direct-supply station at 220 volts, with feeders and distributing system extending 2½ miles, as described above, would be as low as that for an alternating station at 2,000 volts, with transformers and 220-volt lamps, to cover the same area. It would not. Comparing feeders, I think, with the present prices of mains, and using the same class of insulation in each case (as is frequently done now)—that is, not using expensive rubber cables for the high tension—the two systems are equal in cost for feeders 1½ miles long. As the distributing system will extend a quarter of a mile further beyond the end of each feeder, a direct-supply station on exactly the same lines is as cheap in capital cost for an area having a base of at least 3½ miles and covering 10 square miles. Further, as something must be allowed to the direct-supply system on account of lower depreciation, and greater safety and freedom from restrictions, and ability to supply motors more easily, another quarter of a mile may easily be allowed on the feeders of the direct-supply station on this account; so that the systems compare together when the base of the area served is four miles and the area itself 16 square miles, even if no accumulators are used.

Although this is not as large as the area I have taken as a basis, what it means can be estimated from what has been said above as to the actual areas covered by large towns. I am, of course, assuming that 220-volt lamps are used on the transformer station as well as the direct. If we assume that the transformer station employs 100-volt lamps, of course the comparison would be much more decidedly in favour of the direct supply at 220 volts.

There is no need, however, to go very minutely into these figures, because, though thoroughly practical, they do not represent what it is clear will be central station practice in the future, as I do not think it probable that any direct supply station in the future will be operated without accumulators.

The Use of Accumulators.

This brings me to the fifth and last point mentioned at the beginning of my Paper when enumerating the possibilities likely to affect central station practice in the future—viz., *the use of accumulators*. In the earlier part of 1891 I did not see much likelihood of improvements in accumulators making any really fundamental alteration in central station practice. But I must confess that in this respect events have moved faster than I anticipated, although I have been brought sufficiently into contact with them to learn what was going on in the field and how batteries were doing as regards upkeep. Up till comparatively recently there is no doubt accumulators have been rather a luxury and convenience in central stations than a commercial or economical necessity; but during the last two or three years considerable changes have been taking place. The maximum safe discharge rate for accumulators has been going up, while the initial cost has been going down, as well as the cost of upkeep, and extended experience holds out the hope of much longer life for the newer and improved forms of positive plates than has hitherto been the rule. Owing also to the method of supplying accumulators at a maintenance rate adopted by the leading firms, an engineer need have less hesitation in recommending clients to incur a large expenditure on them, and the risk is much less than formerly. Patents are also expiring, and considerable competition is arising in this trade, which was formerly such a close one.

I have lately had to make careful inquiries about accumulators in connection with work on which I am engaged, not only as regards prices, but also as to their working, and, having got particulars about the batteries in several central stations, and held conversations with the engineers concerning them, have been considerably surprised at the progress which has been made. Taking quotations from leading makers for a battery suitable for a central station, I find that the capital cost of a battery to discharge at 1 kilowatt for three hours is as nearly as possible £13 for the battery alone. Several makers assure me that such a battery can be discharged at this, and even higher rates, every day regularly, without detriment or endangering the life of the positive plates. The above price does not include buildings to contain the accumulators, connections, instruments, or stands to hold them, which bring up

Digitized by Google

the cost to about £19 per kilowatt on this basis for central station batteries. The makers tell me further that they are willing to enter into contracts to maintain such batteries in a state equal to new for about 6 per cent. per annum on their capital cost, and some makers will even go lower than this. It will be found that these costs and rates of renewal are a great improvement on those ruling until comparatively recently.

Now I should not quote these figures unless I had, by private inquiries and in other ways, fairly convinced myself of their substantial accuracy. Granting that they are so, it appears to me that they raise questions of very serious import in central station practice, particularly when coupled with the use of higher voltage lamps. If an accumulator will give a discharge for three hours—that is, sufficient to cover the period of heavy load, or the time during which the large portion of the plant has to be kept running—a kilowatt capacity of accumulators will be equivalent to a kilowatt capacity in engines and dynamos. In continuous-current stations, when an increase of output is required—which is from time to time the position of most stations—we are therefore brought face to face with this problem. Extra plant for 200 kilowatts output, say, is required. Which is the best way of providing for it—by adding engines and boilers, or by adding accumulators and charging them during off hours from the existing plant? Now, as I have said above, an accumulator for an extra kilowatt output will cost about £19 complete and erected, including buildings; and I think engineers will generally agree with me that engines, boilers, dynamos and steam pipes for a kilowatt output, including buildings and all other accessories, would cost about the same sum; if foundations, flues, chimney stalk and everything else were considered, the comparison would be slightly in favour of accumulators. However, for our present purpose, let us assume that they are equal. We have therefore arrived at the position that the capital cost will be equal, whether we provide extra plant or extra accumulators for the increased output required, charging the accumulators from the existing plant. As regards upkeep, if we can keep the accumulators in an efficient state for 6 per cent. on their cost, this is not greatly in excess of what would have to be allowed on plant if boilers are included; and, at any rate, the difference is not a matter of very great moment.

There is no need to say anything here on the extremely low cost at which energy can be produced if a continuous load is provided night and day. Considering the advantages accumulators give in a central station in providing for emergencies, reducing staff, and keeping the pressure even, it is, I think, doubtful if an engineer placed in the position indicated above—as many engineers will be placed shortly—would not be wise in recommending his Corporation or his Board to instal accumulators for 200 kilowatts output for three hours, instead of the extra plant, when the plant was a continuous one. How far this should proceed is a moot point, dependent upon circumstances, which would need decision in each case. Possibly somewhere about one-third the maximum full-load capacity would be about right now, but with a load-factor of 10 to 15—which is about that general in central stations—if the price of accumulators came down per kilowatt output, which I think it is likely to do in the future, or their efficiency increased, it might be found desirable to instal accumulators for as much as two-thirds, or even three-fourths, of the full load, which would place electric distribution nearly on a par with gas distribution in respect to storage. To go as far as that is, however, not a question of the present—at any rate in most cases—and therefore for our purpose this evening I propose to consider the accumulators as desirable for about one-third to one-half the full output.

It may be useful here to give a few general data relating to accumulators as they stand at present. The leading makers' prices of central station batteries work out at about £13 per kilowatt on a discharge for three hours, for the plates, cells, and acid only; whilst, including stands, erection, connections, and switching arrangements, the price works out about £17 per kilowatt, or, if buildings also are included, about £19 per kilowatt. In such a battery, I find the plates and lead cells alone would weigh about 8cwt. per kilowatt output on the three hours discharge basis; and that 1cwt. of plates and cells costs a little under £2—or the cost comes to about £40 per ton. Now, as lead costs under £12 per ton at present, and seeing how much almost pure lead, in a very simple form, there is in accumulators, it does not seem unreasonable to anticipate that in the future, when accumulators are made on a much larger scale, we may see the price gradually come down to, say, £25 per ton, with, perhaps, improved capacity and life. At least, it appears to me that there is as good hope in this direction as there is of reduction in price and improvement in quality in any other department of electric engineering. If such a consummation were attained, it is pretty clear that it might pay to use accumulators for power stations, as well as lighting, wherever an eight or nine hours day was in vogue, and that they may ultimately come to exercise a much wider influence on the future of the electric industry than most engineers have anticipated.

In order to gauge in some measure what has been the improvement in accumulators during the last few years, and since the question of the system of central-station supply was last prominently before this Institution, I lately took an opportunity of talking the matter over with Mr. Epstein, and I asked him if by looking up old contracts and catalogues he could give me anything definite on the subject; in reply, he has sent me the following letter:—"I have looked into the question of the prices of accumulators, and I find that, comparing the prices in 1890 with the present ones, there is, on an average, a reduction of 25 per cent. But another and more important point is this—that whereas the types then manufactured were only allowed to be discharged in about 10 hours, necessitating in the case of shorter discharges much larger batteries than required for the purpose, the discharge rate has since then increased very considerably. Taking one with the other, I think I am justified in saying that the reduction altogether amounts to quite 50 per cent." In view of these facts, and considering that it is now the custom to buy accumulators on a moderate maintenance agreement, and also all the added experience of the last five years' work, it will be at once evident on how much sounder a basis commercially accumulators now rest, and how much stronger the arguments in favour of their employment in central stations are than they formerly were.

Upon the three hours discharge basis, I find a kilowatt capacity of accumulators occupies approximately 4 cubic feet space, for the cells and connections, so that we get a kilowatt-hour into 1·33 cubic feet. Now a discharge of a kilowatt-hour, allowing for losses, will keep about 15 16-c.p. lamps going for one hour. Allowing that a gas burner using 6 feet of gas per hour is equal to a 16-c.p. lamp, the amount of space needed in a gasometer to store gas for the same amount of light is $6 \times 15 = 90$ cubic feet, or 70 times as much space. Of course this is not quite a fair comparison, because nothing is allowed for stands, access, &c.; but I think it will be quite fair if we allow ten times as much space for access, &c., as the accumulators take themselves. Even under these, the actual conditions, accumulators only occupy one-seventh the space which the equivalent gasometer would. We arrive, therefore, at the curious conclusion that, if the London gasometers were emptied of their gas and fitted up as accumulator rooms, sufficient accumulators for lighting London could easily be arranged under working conditions in one-seventh of the space which would be available. We have, therefore, nothing very enormous to fear in the way of accumulator houses, even if accumulators are used in the future on the most extensive scale for lighting or power purposes.

Interesting as these speculations are, it is desirable, however, to return to what is more specifically our subject. It is usual at present to place the accumulators in the central station, except in a few instances, such as in Mr. King's system at Chelsea, Mr. Parker's Oxford system, and a few special places. Usually under these circumstances the accumulator is subject to the heavy drop at full load, which decreases its efficiency by 10 to 15 per cent. With 220-volt lamps the drop on the feeders within a mile radius would be much less than is usual now, and therefore the value of the accumulators would be correspondingly increased. For longer distances from the central station than a mile, however, undoubtedly the right place in most cases for accumulators will be at the feeder points. This is the more feasible with 220-volt lamps than under present practice, because the distributing network is so much larger from each feeder, and each feeder becomes the centre of a serious amount of lighting, which will pay for individual attention. Although from the table I have given the cost of copper per lamp installed for feeders is very moderate, yet on a two-mile feeder it amounts to a considerable sum in the aggregate; and if, by installing accumulators at the end of the feeder for one-third to half the full output, the section of the feeder can be cut down by one-third or a half, a very important saving is effected; and, of course, if accumulators for two-thirds or three-fourths full load were installed, the cost of feeders would be correspondingly reduced. This has already been recognised in practice, and many devices have been brought out for charging accumulators in series, or by the help of motor transformers using a high-tension current; but I would point out that the use of 220-volt lamps on a three-wire system does away with the necessity for any of these complications. All that is needed is a continuous-current motor transformer of the "booster" type. In this, one armature circuit is across the mains, and wound with a high resistance and many turns, while the current to the accumulators passes through the second circuit direct; the second circuit being wound with a few turns, so that the voltage of the main current in passing through the armature is raised, say, 30 per cent. The motor transformer then need only be about one-third the capacity for the charging current, and the cells can be charged at any time, while the circuit is supplying lamps, so that continuity of supply without complication is ensured. By these means the cost of long feeders would be much reduced on the figures given above; which means also that it would be practicable to extend the lighting radius much further than was contemplated above at the same cost, should it be needed. An important factor

Digitized by Google

is also brought in—that, having once laid a feeder of fair size, accumulators can be added at the outer end as the lighting grows, and thus a very large increase of lighting could be gradually met without relaying the feeder or disturbing the streets, which is always an expensive and troublesome operation.

In what I have said above I have indicated a feeder to each half square mile as an average, or four to the square mile; but it is clear that, if accumulators were employed, and it were desirable to concentrate them in order to save labour and attendance, it would be very simple to run short sub-feeders from a centre, so that one distributing point where accumulators were situated, and one feeder from the central station, could be economically made to serve a square mile or more.

It is further worth noting that at 220 volts the cutting in or out of a cell makes less than 1 per cent. difference in the voltage, and not 2 per cent., as at present. This is an important consideration in keeping the light steady, a point the importance of which is becoming more and more recognised.

The convenience of the system for arc lighting does not need pointing out, as nine arc lamps can be run in series. One more point is the effect which a general electric supply at 220 volts on the lines indicated above would have on the power supply question. There is no difficulty in procuring already motors of any size, from 50 watts upwards, to run on 220-volt circuits, the number of amperes they take being, of course, half what is usual now; while for larger sizes, say, above 3 or 4 kilowatts, they could, of course, be coupled across the two outers at 440 volts. If we then add the facts that the drop on the feeders would be less than at present, that the current-density in the distributing system on the basis I have laid down would only be about half what it is at present—and when we consider that there would only be 1½ per cent. fall of pressure at full load on the distributing mains, and that by cross-coupling even this would be reduced—then it seems to me that it goes almost without saying that motors could be used to a far greater extent than at present is possible without appreciably affecting the regularity of the lighting. Accumulators at the feeding points would also be an important aid in this respect; if they were so used, the fall of voltage from them to the motors would rarely exceed 2 per cent., and under such circumstances motors of considerable size could be started and stopped (even without special starting resistances) without the rush of current being perceptible on neighbouring lamps. In this respect, therefore, the use of 220 volts is likely to be very advantageous, and do away with the necessity of having to lay special power mains—for some years, at any rate.

The utility of having generators in the lighting stations giving the current and voltage which is needed for tramway work is also obvious; in fact, it looks as if one station in future would do all the power supply for a town, the lighting being only one adjunct of its business, and that, possibily, not the largest. With most of the lighting done by means of accumulators charged during the night, and the station supplying power to the tramways, &c., during the day, it ought to be possible to secure a very fairly even all-day load with one set of plant, instead of two as at present. This would, of course, lead to important economies in generating expenses. In fact, it looks as if we could already see far enough ahead practically to enable Mr. Preece's prophecy to be fulfilled in a moderate time—"that the electric light would ultimately be the light of the poor man as well as of the rich."

And now I must conclude. The title of my paper was "High-Voltage Lamps, and their Influence on Central Station Practice." In the first place, I have endeavoured to show that high-voltage lamps are thoroughly practical. Next, that high-voltage lamps are more desirable than lamps of the usual voltage and of high economy. I have also shown reasons why it is probable that the economy of high-voltage lamps may in time nearly approach that obtainable in ordinary voltage lamps.

Having thus tried to establish the soundness of the position of the high-voltage lamp itself, I went on to consider what influence the adoption of a high-voltage lamp would have on central station practice. I have shown how it simplifies and renders less costly the distribution of current, and how it improves the conditions of lighting. I think I have further made it fairly clear that for nearly all practical requirements of town lighting the direct supply system will prove simpler and less costly, as well as more advantageous, than any system, whether direct or alternating, in which transformers are used; in fact, the necessity for this class of apparatus, except for special cases, seems to vanish.

I think, therefore, that, when the facts are fairly faced, there does not seem much doubt that those engineers who have advised their clients to erect continuous-current direct supply stations in the past have done wisely, and will be found to have served their clients' best interests; and that for the future alternating-current stations, even for country towns and scattered districts, should only be erected after the most careful weighing of possibilities.

It is considerations of this character which have led me to keep very much in the background as regards central station lighting for the last four years. Having been associated from the early days with alternating currents, my predilections were in that direction; and although the position seemed secure, yet, seeing the possibility of great improvements in several directions which would tell strongly in the favour of direct supply (but the exact advent of which no one could actually foretell until it arrived), it seemed to me more prudent to turn one's attention to other things for the time than to incur the risk of recommending work which might soon have to be undone. I have always expected and looked forward to a time when there would be one system of lighting, with variations merely in details, and have felt that the rivalry between the two systems would some day end as the battle of the gauges ended in the early railway days, and I think there are signs of the end now. It seems as if the narrow gauge would win again—as if the tortoise would again beat the hare, though it is true that to do so the tortoise has had to improve its pace considerably.

TESTS OF RAIL BONDS.*

The following resistance tests of rail bonds were recently made at the power house of the Buffalo Railway Company, and the results will be of much interest to railway engineers:—

Type of bond.	Size of girder rails used. Lbs. per yard.	Current in amperes.	Drop in bond. Volts.	Condition of bond at end of test.	Remarks.
Copper bond.	90	125	0·0375		With one No. 00 bond 6in. long, through rail base. Contacts clean, tight and new.
		1,200	0·208		
		1,450	0·313	Very hot.	
Ditto.	Ditto.	200	0·028		With one No. 0 copper wire 30in. long, newly fastened with channel pins.
		1,200	0·178		
		1,500	0·21		
Plastic bond.	Ditto.	160	0·002		With standard type of plastic bond between web of rail and angle-plate on one side only.
		200	0·01		
		1,200	0·035		
		1,400	0·04	Cold.	
Plastic plug bond.	62½	190	0·00426		Rails on chairs with T-rail under joint; one pair of §in. holes through chair and rail base into top of T-rail; holes amalgamated and filled with plastic alloy.
		400	0·0201		
		1,200	0·0623		
		1,500	0·086	Cold.	
Ditto.	Ditto.	190	0·00186		Ditto, with one pair of §in. holes on each side of rail; amalgamated and filled with plastic alloy.
		1,200	0·0428		
		1,300	0·0422	Cold.	
Ditto.	Ditto.	200	0·0026		With horizontal hole §in. diameter in meeting ends of rails, with grooved steel dowel pin; amalgamated and filled with plastic alloy.
		1,000	0·038		
		1,300	0·0554		
		1,500	0·067	Cold.

ST. PANCRAS VESTRY WIRING RULES.

CURRENT WILL BE SUPPLIED AT 220 VOLTS.

Special attention is called to Rules Nos. 3, 4, 5, 6, 10, 11, 12, 13, 14, 17, 22, 33, 39 *and* 40.

1. *Conductors.*—All conductors must be of tinned copper, of not less than 98 per cent. of conductivity (by Matthiessen's standard). They must be so proportioned that the current density in no case exceeds the rate of 1,000 amperes per square inch of sectional area.

2. *Limit of Conductors.*—No conductor to be smaller than No. 18 S.W.G. Conductors larger than No. 16 S.W.G. must be stranded.

3. *Insulation Conductors.*—The insulation resistance of every cable or lead must not be less than at the rate of 2,500 megohms per statute mile, after one minute's electrification. All rubber-covered conductors must have a coating of pure rubber, and one of vulcanising rubber, and the whole properly vulcanised and braided, or otherwise suitably protected against mechanical injury.

4. *Conductors under Plaster.*—Conductors buried under plaster must be protected by iron piping (where practicable) or porcelain ducts.

5. *Conductors in Wet Positions.*—Conductors in wet situations should be, by preference, in porcelain ducts. If in wood casing, care must be taken to leave an air space of ⅛in. between the casing and the wall, and the vulcanised rubber-covered conductor must be further protected by a covering of lead.

6. *Casing Corners, Rounded.*—Where casing is used all corners must be well cut away and rounded to avoid damaging the insulation of the conductor.

7. *Conductors Outside Premises.*—Conductors outside buildings should be supported on porcelain insulators at frequent intervals, and kept about 8in. or 10in. apart.

8. *Naked Conductors.*—No naked conductors allowed.

9. *Staples Forbidden.*—No staples to be driven over conductors.

10. *Joints Soldered—Resin only to be used.*—All joints must be soldered and thoroughly sweated together, nothing but resin as a flux permitted. Soldering-irons are to be tinned with resin, *and no sal ammoniac used.*

11. *Insulation of Joints—Joints Vulcanised in Wet Positions.*—After soldering, each end for not less than 2in. on either side of the joint must have all tape, cotton, or braiding removed, laying bare a clean rubber surface, which is to be carefully tapered down. The whole of the joint and bared rubber must be covered with at least five lappings of pure rubber tape, and two or more of prepared vulcanising rubber tape; the whole to be tightly bound with prepared waterproof tape, and in damp positions, or covered by plaster, to be properly vulcanised or otherwise rendered permanently watertight. If the vulcanising be found impracticable in certain positions, the finished joint should be coated with shellac varnish. Rubber joints will not permanently resist moisture unless vulcanised.

12. *Joints Kept Apart.*—Every joint or branch tapping must be kept at least 8in. from those of opposite polarity.

13. *Preparation of Ends of Conductor.*—All ends of cables or conductors, before being connected with fittings, must have the tape or braiding removed, leaving a clean rubber surface for at least 1½in.

14. *Main Circuits.*—Should the current demanded exceed 25 amperes, two separate and distinct main circuits must be run in two casings to the terminals of the Vestry's supply. These circuits should supply alternate floors of the building, in order to keep them as far as possible distinct.

15. *Loop left for Meter.*—In every main circuit a loop having five feet of slack cable must be left at the proper position for the insertion of the meter.

16. *Main Fuses—Positions.*—The contractor must fix a main single pole fuse on every main conductor, at the point immediately after leaving the meters to the house. The fuses for the mains completing the circuits are to be inserted between the Vestry's main switches and the house side of the circuit.

17. *Tin Fuse Bridges Stamped.*—The fuse bridges for these main fuses must be adjusted to carry less than those fixed by the Vestry. They must be of flat tin, stamped, indicating the working current, *and have at least* 1½*in. of clear break.*

18. *Branches—Two Fuses For.*—Every branch circuit shall be efficiently protected by two distinct fuses, one on each pole, at the point of juncture.

19. *Fuse-Boards.*—If distributing fuse-boards are employed there must be two distinct boards—the one negative, the other positive—under separate covers, kept at least 4in. apart.

20. *Double-Pole Fuses Prohibited.*—Double-pole safety fuses will not be permitted on any account.

21. *Area of Fuse Bridges.*—All fuse bridges must be of tin, and must not, under any conditions, exceed the sectional area of the circuit they are intended to protect.

22. *Design of Safety Fuses.*—All safety fuses must be mounted on porcelain or vitrite bases, with covers of similar material. *The break must be not less than* ⅜*in., nor may the distance between any portion of the metal or conductor be less.*

23. *No Fuses under Floors.*—No fuses allowed under floors.

24. *Switches.*—Switches in close proximity *must be all of the same polarity.* All switches must be quick break, mounted on an insulated base of porcelain, vitrite, or slate boiled in paraffin wax. They must be so designed that the action is certain, either "on" or "off," and cannot possibly remain in an intermediate position. The handles and covers must be well insulated from the circuit.

25. *Switches for Arc Lamps—Main Switches.*—Switches controlling either arc lamps or main circuits should have at least one inch of clear break.

26. *Switches on Fittings.*—Switches forming part of fittings must be well insulated. The handles must also be insulated from the circuit. No combination fuse and switch allowed.

27. *Limit of Lamps for Switch.*—Not more than 10 16-c.p. lamps, or their equivalent, to be controlled by each switch, except by special permission in writing from the engineer. Lamps consuming more than the equivalent stated, must be provided with a switch to each.

28. *Arc Lamps Insulated.*—Arc lamps must be suspended by porcelain insulators. Four ordinary arc lamps are required in series for the 220 volt supply. If two only are required they must be of suitable design.

29. *Fix Incandescence Lamps in a Vertical Position.*—Incandescence lamps should be fixed with the bulb in a vertical position. For other positions lamps must be used in which the filaments are specially supported.

30. *Resistances.*—All resistances should be mounted on iron frames kept 18in. clear of all woodwork or inflammable material. They must be protected by a metal guard, and supported on insulators. The conductors leading thereto should pass upwards, and be connected with terminals at the lower portion of the frame, so as to avoid contact with any heated part. Resistances should be fixed on brick walls, or by preference hung outside of the building.

31. *No Exposed Parts Allowed.*—No portion of the electric circuit, or of metallic fittings or parts in connection with the circuit, more especially in switches and cut-outs, to be left exposed.

32. *Earth Connections.*—No metal frame work of any fittings shall be used as part of the electric circuit, or be in contact therewith, and no connection with gas, water pipes, or "earth" allowed.

33. *Combination Fittings.*—Combination gas and electricity fittings *must not be employed*, except by special consent of the Engineer, and under such precautions and conditions as he may direct.

34. *Wall Plugs, &c.*—Wall plugs, ceiling roses, and other fittings of the kind not specially mentioned, must be mounted on porcelain or vitrite, with covers of similar material. All slate bases to fittings must be soaked in wax. *All porcelain must be vitreous throughout.*

35. *Removal of Fittings—Ends Sealed.*—Should any fittings or apparatus need removal, the ends of the conductors leading thereto must be properly insulated and securely sealed up, and, if practicable, both branch fuses removed. All terminal ends of wires and cables must be thoroughly insulated and sealed up.

36. *Insulation of Complete Installation.*—The insulation resistance in ohms between "earth" and the complete installation, measured at the Vestry's main terminal fuses, with every lamp, fitting, or other apparatus connected, must not be less than the number found by dividing 10,000,000 by the total amperes required to feed the installation.

37. *Testing Fees.*—On receiving due notice in writing of the completion of the wiring, the work will be inspected and tested free of charge. If the first test fails to comply with the requirements herein specified, a second and all subsequent tests will be made on payment of 10*s.* at the offices of the department for every such test.

38. *Low Insulation.*—Should the insulation at any time fall below the standard specified herein, the Vestry may, after due notice, discontinue the supply of electricity to the premises.

39. *Examination of Work.*—The Vestry shall have the right to require the contractor *to open any joint, or to remove any casing, wires, or fittings, for the purpose of ascertaining if the work has been thoroughly executed.*

The contractor must reinstate, at his own expense, any work the Vestry may have examined in the manner set forth.

40. *Additions to Lighting.—No addition shall be made to any installation* that has been tested by the Vestry's officials, *until due notice has been given* on a form to be obtained at the offices of the Department; failing this, the supply is likely to be stopped.

41. *Cut off Current during Repairs.*—Before commencing any extensions, alterations, or repairs to the installation, the main switches must be turned off to avert accidents, and remain so until the work is completed.

42. *Fire Insurance Rules Observed.*—Work on consumers' premises must be strictly in accordance with the rules of the fire insurance companies and of the Institution of Electrical Engineers.

43. *Motors—Starting Resistance.*—Every motor must be wound to work at 220 volts. It must be provided with a suitable starting resistance, so arranged that *it is not possible to disturb the neighbouring lighting when stopping and starting; an automatic water resistance will be preferred.*

44. *Fly-Wheel to Motor.*—Motors driving lifts, cranes or circular saws must be provided with a suitable fly-wheel.

45. *Furnish Details as to Motors.*—Before commencing to fix any motor the following details must be sent to the Engineer:—(*a*) a descriptive drawing of the starting apparatus, giving full details of its action; (*b*) state horse-power; (*c*) purpose for which the motor is required; (*d*) state revolutions per minute; (*e*) diameter of fly-wheel proposed. Thickness and radial depth of rim.

46. *Current for Storage Batteries and other Purposes.*—If current is required for storage batteries or special purposes, the general arrangement of the installation must be submitted to the Engineer for approval.

47. *Non-liability.*—The Vestry do not take any responsibility for the proper execution of any work on consumers' premises, nor for any loss or damage which may be occasioned by fire or any accident arising from the wires, fittings, or other apparatus within the buildings.

48. *Amendments.*—The Vestry reserve to themselves the right, without notice, of altering these rules and regulations from time to time as they may deem necessary.

Previous rules cancelled.

SYDNEY W. BAYNES
Chief Electrical Engineer.

February, 1896.

Digitized by Google

NATIONAL TELEPHONE COMPANY'S STAFF DINNER.

A gathering, numbering nearly 200, and consisting chiefly of members of the staff of the National Telephone Company, sat down to dinner in the King's Hall, Holborn Restaurant, London, on Friday last, the General Manager of the Company (Mr. W. E. L. Gaine) occupying the chair, supported by the Right Hon. Lord Harris (Vice-President of the Company), Sir Albert K. Rollit, M.P., Mr. W. C. Quilter, M.P., Mr. C. S. Agnew, Mr. Geo. Franklin, Mr. G. H. Robertson, Mr. W. A. Smith, Mr. Frank Crisp, Mr. W. H. Preece, C.B., Prof. D. E. Hughes, Mr. J. C. Lamb, C.B., C.M.G., Sir Robert Hunter, Mr. H. C. Fischer, C.M.G., Mr. D. Johnstone Smith, Mr. E. W. Chetwynd, Mr. H. E. Clare (Town Clerk of Liverpool), Mr. R. E. Fox (Town Clerk of Blackburn), Mr. J. Gavey, Mr. J. Hookey, Mr. Geo. Sutton, Mr. J. E. Kingsbury, Mr. Max Binswanger, Mr. James Taylor, Mr. G. Binswanger, Mr. J. T. Crowe, and of the prominent officials of the Company, Messrs. Albert Anns, Dane Sinclair, S J. Goddard, C. B. Clay, J. C. Chambers, R. H. Claxton, A. E. Cotterell, A. Coleman, F. D. Watson, C. J. Phillips, G. F. Preston, F. Gill, R. Shepherd, T. Fletcher, W. V. Morten, R. A. Dalzell, H. Davis, J. W. Ullett, A. Martin, W. A. Valentine, H. B. Sutcliffe, C. G. Wright, W. W. Cook, and many others well known in telephonic circles.

The proceedings were opened by the Chairman proposing the usual loyal toasts, which were cordially accepted. "The Houses of Parliament" was responded to by Lord Harris on behalf of the House of Lords and by Sir Albert Rollit for the House of Commons. An opportunity was taken by the latter speaker to express his views somewhat strongly on account of having been detained in the House until the very moment when, dinnerless, he was called upon to respond to the toast. Both speakers referred in cordial terms to the unanimity now prevailing between the Post Office Department and the National Company. Sir Albert's speech was in his happiest vein and the hon. member was heartily cheered upon resuming his seat.

The CHAIRMAN then proposed the toast of "The National Telephone Company," and in doing so expressed his regret, and that of all present, at the absence of their President, Mr. James Staats Forbes, who, as on the last occasion of their dinner, was strictly forbidden by his medical attendant to be present. Mr. Gaine referred to the serious loss the Company had suffered by the death of Mr. A. Calder, the metropolitan manager, who rose to the important position he filled in the Company's service purely by his own merit. During the past year the *clientèle* of the National Company had been increased by nearly 9,000 subscribers, after allowing for the loss by death and other causes of many who had ceased to subscribe to the Company's system. About 50 further exchanges had been opened during the year, and the total number of messages passing over the Company's wires represented 313,000,000 per annum. The officials of the Company had been engaged in perfecting the machinery and plant of the system and bringing it into a perfect and efficient condition. Much of the plant had been remodelled and brought fully up to date. He referred to the negotiations which had been proceeding with the Post-office for the acquisition by that department of the Company's trunk lines. They had now reached a position when the Government were taking these trunk lines over, and he was able to announce that on April 4th next the telephone trunk wires of the kingdom would begin to pass into the hands of, and belong to, the State. He took that opportunity of assuring the representatives of the Post Office who were present that the easy working of the trunk lines by the State would be assisted by the staff of the National Company by every means in its power. They could depend upon the most cordial and loyal support from all concerned. He was not prepared to say that if they had been left to themselves they would have invited the Post Office to acquire the trunk lines, but it having been determined by Parliament that this should be done, and the negotiations having now satisfactorily terminated, it would be the policy of the Company to render every possible assistance to the Department in the carrying out of this important work. This brought him to the future position of the National Company. They would still continue to undertake what might be termed the local telephone service of the kingdom, and he therefore regarded the relationship now to exist between the two bodies as in the nature of a partnership. The local service could be nothing without the trunk service, the trunk service could not exist without the local service. This position imposed upon the Company —upon its Directors and upon every officer of the Company—very grave responsibilities. He was happy to think that the Board of Directors had decided to take the most enlightened view of that responsibility, and were determined to join with the Post Office in making the telephone service as perfect as modern science and practice could make it. He desired to say that in all the great towns of the kingdom, if the Local Authorities were prepared to give the Company reasonable and adequate facilities, the Company on its part was prepared to place the whole service on the metallic circuit principle. It was an essential feature of the quasi-partnership between the State and the Company that the State Department should confine its attention principally to looking after that portion of the business which it had taken in hand, and not to look too carefully after or to enter on that portion of the business which it was the function of the junior partner (the Company) to conduct. He had stated at the last staff dinner that the very essence of the telephone service was a monopoly, in the sense that it could not be in more than two hands, and his opinion still was that, if the public was to be properly served, the "partnership" could not admit other bodies to the arrangement.

Lord HARRIS, in response, returned his personal thanks, and those of his colleagues, for the cordial response which had been been accorded to the toast, and desired to give expression to the feeling of comradeship which he and all associated with the administration felt existed with the staff connected with this great undertaking. Although the junior member of the Board, no one was more impressed with the spirit of loyalty that animated the staff of the National Company. The undertaking was an immense one, and when they realised the different and conflicting interests which had to be satisfied, he claimed for the Company a large measure of success. Not only had the public to be satisfied, but their large body of shareholders also claimed a full share of their attention. They were an important body, and it was due to their confidence and their commercial enterprise that the Company had attained its present successful position. The shareholders, at their recent meeting, had expressed no dissatisfaction with the system of administration. As to the public he did not claim that under the circumstances and the very material changes which were going on in the distribution of the material parts of the service that entire satisfaction had been given, but he believed that the result of the labours of their experienced engineers and officials would be that the public would ultimately have a service as perfect as human ingenuity and scientific methods could make it. They were striving their utmost to serve the public well and to give, in conjunction with the Post Office, the best possible means of intercommunication between telephone subscribers and other members of the public all over the country. In future instead of any jealous competition between the two branches of the telephone service the competition would be only as to zeal and efficiency. When he considered how great was the responsibility thrown upon the Directors and the Company for its efficient and successful working, he felt the more grateful to those who bore the heat and burden of the day, the Staff of the Company, chief amongst whom was their friend in the chair, Mr. Gaine. He could speak of the valuable services which Mr. Gaine had rendered to the National Company, and they were grateful to him as chief of the staff for the efficient service which was provided. His Lordship, in conclusion, referred to the vast numbers of employees of the Company, who were administering to the convenience of the public, and were doing their work honestly and well (the lady operators), and he appealed to those using the telephone to treat this hard-working and indispensable branch of the service with all possible courtesy and consideration. They were conducting an intricate service, and, upon the whole, were deserving of all praise for the success which attended their endeavours.

Mr. DANE SINCLAIR then proposed "Electrical Science," coupling the toast with the name of Mr. W. H. Preece. He referred to the successive steps, which since the middle of the seventeenth century had brought them to their present knowledge of electrical matters. When between the years 1821 and 1831 the development of electrical science brought in its wake the telegraph, many people thought that science had achieved all that could be expected of it. This was not, however, the view of such men as Franklin, Cavendish, Volta, Oersted, Faraday, Ampère, Davy, Henry, Thomson (now Lord Kelvin), Hughes, and many others whose names were familiar to them, who continued their investigations and brought electrical science up to its present point of perfection. Their thanks were especially due to such workers as Lord Kelvin, who had produced such splendid instruments as the syphon recorder, and had done so much to enable workers in the electrical industries to overcome the many difficulties which threatened their success at every turn. Looking to the marvellous progress which had been made by electrical science in the past few years there was no telling the wonderful achievements which would ultimately result from the experiments and discoveries of the present day.

Mr. W. H. PREECE, in response, said he was very proud to have his name associated with the toast of electrical science. For 44 years he had been working hard at the applications of this science. His earliest ideas were gathered at the feet of Faraday. From the day that electricity was regarded as a mystery to the present time, when it is regarded as a pure and distinct science, the spirit of Faraday had hovered over every electrician. He had himself been associated with almost every application of electricity to industrial purposes from the first introduction into this country of electric bells to the present time. He looked around him that night and saw so much youth working hard and striving hard to acquire further knowledge of the mysteries of electricity, and he could not help feeling that there was here a potentiality of invention which was going to mark a progress in the future far greater than that of the past. With regard to the remarks made by previous speakers as to the cordial arrangements henceforward to exist between the Post Office and the National Company in carrying out their joint undertaking, he was sure these sentiments would be reciprocated by the officials of the Post Office, not only those present, but those who were absent. The result would be that the telephone service of this country, controlled in one direction by the Post Office, and worked in the other by the National Company, would be, must be and should be the best telephone service in the world. They lived in a period of high pressure, and were going ahead at a break-neck pace, but there was one comfort behind it all—they had to aid them a branch of science that at any rate was going to cement friendship and add happiness, comfort, and health to their surroundings.

Mr. W. A. SMITH then proposed "The Post Office," and after paying a passing tribute to the memory of the late Sir Henry Calcraft, spoke of the good work done for the State by officials of the Post Office and to the satisfaction which all concerned felt at the happy termination of the negotiations between the Department and the Company.

Mr. J. C. LAMB, in reply, thanked them for the cordial manner in which the toast of "The Post Office" had been received. For himself, he looked upon the Post Office Department much in the same way as a sailor looked on a good ship; he was concerned in its reputation, and he wanted to see it standing as high in the estimation of everybody as possible. He was, therefore, not sorry to be allowed to respond to the toast. The Department brought him daily into contact with the representatives of the great commercial undertakings of the country, including the railway companies, the cable companies, and now the Telephone Company. Unfortunately it was not possible always to agree with the gentlemen who represented

Digitized by Google

these important interests, but he was glad to be able to entertain the feeling that they were the representatives of legitimate and important British industries. He was expressing his own feelings and those of his colleagues, he was sure, in saying that they would be pleased and proud to work alongside the representatives of the National Company in conducting the telephone service of the country.

The remaining toasts were "The Board of Directors and other Guests," proposed by Mr. F. D. Watson and responded to by Mr. Quilter, M.P., and "The Staff of the National Telephone Company," proposed by Sir Robert Hunter and responded to by Mr. Albert Anns.

During the dinner an excellent selection of music was provided, and the company did not separate until a late hour.

PARLIAMENTARY INTELLIGENCE.

THE STRAND DISTRICT ELECTRIC LIGHTING.

Yesterday (Thursday) at the House of Commons, Sir J. Kitson's Committee on the Electric Lighting Provisional Orders (No. 4) Bill considered the Strand District Electric Lighting Bill, which has been sent down by the House of Lord's Committee. By the Bill it is proposed to confirm a Provisional Order made by the Board of Trade under the Electric Lighting Acts 1882 and 1888 to the Charing Cross and Strand Electricity Supply Corporation (Limited), in respect of the district of the Strand District Board of Works. Mr. Pember, Q.C., Mr. S. Wills, Q.C., and Mr. Claude Bagally appeared for the promoters. The Metropolitan Electric Supply Company (Limited) petitioned against the Bill, and were represented by Mr. Balfour-Browne, Q.C., and Mr. Fitzgerald, Q.C.

Mr. PEMBER, in opening for the promoters, said that in May, 1894, the Charing Cross Company sent a request to the Strand District Board of Works for their consent to a Provisional Order for the Parish of St. Paul's, Covent Garden, and for that district only. There were special reasons why that course should be taken, as he would show. The request was referred to the Works Committee, who in the same month made a report that the competive powers which were sought should only be given on condition that similar powers were sought for the whole of the district. That was an intelligible position to take up. The view was that if any part of the district should have the benefit the whole should have it, and that the benefit should be bestowed simultaneously, and not piecemeal. Conferences then took place between the Company and the Board of Works, and the former was recommended to amend their memorial. Ultimately, on October 3, 1894, the Works Committee reported to the Board to the effect that the Company should have similar powers to those enjoyed by the Metropolitan Electric Supply Company, which was established in the district. The Charing Cross Company naturally had no objection to embracing the entire area. In the month of October, 1894, the whole body of the Board of Works confirmed the report, and consent was given. The promoters then gave their notices, and a draft agreement was submitted. The negotiations were conducted on the basis of the clauses in their Provisional Order being substituted for the agreement which was originally asked for. These clauses were agreed to by the promoters, and the Company gave the ordinary undertaking to obtain the insertion of these clauses by the Board of Trade in the Provisional Order. In 1894, then, consent was obtained conditionally, and on April 10, 1895, consent was obtained on the undertaking that the Company would, to the best of their ability, secure the insertion of the clauses in the Board of Trade Provisional Order. Subsequently, however, a meeting of the Board of Works was held, attended by 26 out of the 49 members, and a resolution was passed revoking the sanction given, but the members present were not sufficiently numerous to render the resolution valid according to the bye-laws. That was a very strange change of front, and it was easy to understand that considerable pressure must have been used; and it was also easy to understand from what quarter the pressure came. A large and influentially-signed petition had been presented by the inhabitants of the district, who stated that they would benefit both in regard to price and quality by the advent of the Charing Cross Company. In 1889 Major Marindin, of the Board of Trade, held an inquiry concerning the advantages and disadvantages of the alternating system and the direct system of electric supply, and in his report he spoke favourably of competition, and recommended that where possible that competition should be between an alternating and a direct company. It was therefore to be hoped that the promoters would succeed in getting the Bill, and thus give the Strand the benefit of the two competing systems. The petition of the opponents was very much the same as that submitted to the House of Lords, except that one or two alterations had been made. The petitioners urged that under the Order of 1889 they had, at very great expense, constructed works and laid mains for the supply of electricity throughout the Strand district, and that by the exercise of the powers contained in the Provisional Order their undertaking would be injuriously affected: they would be subjected to a severe and unfair competition, and their mains, pipes, and lines would be liable to be altered, removed and interfered with to their great loss, and to the serious inconvenience of their customers and the public. Their expenditure had already reached the large sum of over £100,000 for the Strand district alone, and the shareholders had up to the present received but a very small return. In the years 1889, 1890 and 1891 no dividend was paid; in 1892 the first dividend was paid at the rate of 2 per cent.; for 1893, 2½ per cent. was paid; and for 1894, 3 per cent. Counsel, however, contended that that was no reason why the promoters should not have their Bill. The Board of Trade recognised the advantage of competition, and the consumers were of the same opinion. The laying of the mains through the streets was a matter of strict regulation, and the suggestion that the rival company's mains and wires would be injured was ridiculous. The petitioners also urged that there was no public necessity for the confirmation of the Provisional Order, as they were able and willing to supply with electricity any persons within the Strand district, and that their mains were actually laid in the streets mentioned in the second schedule to the Provisional Order. Therefore, any capital expended by the Charing Cross Company in laying duplicate sets of mains where one set was sufficient and already laid represented a wasteful expenditure, for which the public, in one shape or the other, would have to pay. He (Mr. Pember) thought there was no solidity in that argument. In the opinion of the consumers, the Metropolitan Company was not able to supply all that was required, and 700 of them had stated so by signing the petition which had been presented.

Mr. EDWARD WILMOT SEALE, examined by Mr. Wills, said he was General Manager and Secretary of the Charing Cross Company. They worked on the direct low-tension system, with 100 volts, while the Metropolitan Company used the alternating high-tension system with 2,000 volts. His Company had had several applications to supply in the Strand district, and that was the reason they had promoted the Bill. The petition to the House in favour of the Company entering the district had been signed by most of the influential ratepayers. He was sure there would be no difficulty in raising the additional capital which would be required, and they had already deposited £1,000 with the Board of Trade as a guarantee that they would carry out the works necessary. So far the operations of the Company had been attended by uniform success. In some districts his Company were already working in competition with the Metropolitan Company, and except in one trivial instance there had never been any difficulty connected with the laying of the mains. In the St. Martin's district they already had 22 miles of wires.

Cross-examined by Mr. Balfour-Browne, WITNESS said that in the event of any accident happening to the works of one company it was a great advantage to a district to have another company on which they could fall back.

Re-examined, WITNESS said his Company had not the slightest intention of combining with the Metropolitan Company.

Mr. W. H. PATCHELL, examined by Mr. Wills, deposed that he was chief engineer to the Charing Cross Company. The alternating current supplied by the Metropolitan Company was not suitable for motive power, and that was the reason why large consumers, who desired motive power, wished his Company to come into the district. In laying down their mains they used Callender casing, which enabled additional wires to be drawn through without breaking up the streets. There had been no difficulty between the two companies in the St. Martin's district, and he did not see why there should be any in the Strand.

Cross-examined by Mr. Fitzgerald, WITNESS said the original desire of the Company was to supply the St. Paul's district, Covent Garden, but now they desired to supply the whole of the Strand.

Other evidence having been given, the Committee adjourned.

CORRESPONDENCE.

RÖNTGEN RAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Last night I received the following telegram from Edison, which, I am sure, will interest your readers:—

"Just found calcium tungstate properly crystallised gives splendid fluorescence with Röntgen ray, far exceeding platino-cyanide, rendering photographs unnecessary.—(Signed) "EDISON."

—Yours, &c., KELVIN.

March 17, 1896.

ELECTRICAL STANDARDS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The question of accuracy of electrical measurements is daily becoming of more importance. Now that electrical supply undertakings are settling down to economical work, the values of the three units of electromotive force, current and resistance require to be known to a much finer degree of accuracy than hitherto, and therefore users of standards begin to look to somebody whose opinion and certificate on such values shall be final, as is now the case with the yard and the pint pot.

Of the three units, that of resistance is the only one which can be made so to speak in "solid form," and I think in this country something has still to be done in the matter of certifying such units. Suppose that a maker has a piece of metal joined to two large terminals, and he says that when 100 amperes are passed through the arrangement there is a fall of potential of one volt between the terminals; in the case of some makers and some customers this statement is sufficient, but what happens if it is not?

Digitized by Google

At the Cavendish Laboratory units of the original B.A. form, down to 0·1 ohm. are certified at a truly marvellous range of temperatures down to convenient values, such as 11·7°C., 13·1°C., &c., for a charge of 21s.; our Board of Trade Electrical Department courteously offer to test standards, but as yet unofficially and without fee. This, of course, makers cannot take advantage of, except to check their own standards from time to time.

A contrast to this is the Physikalische Reichsanstalt in Berlin, where standards of values varying from 0·0001 to 10,000 ohms are dealt with in a most businesslike style, at an average cost of 8s. only. Two values are given in each certificate, one at 15°C. and one at 25°C., and also the temperature coefficient between these limits. Surely, it is hardly fair to British manufacturers that the facilities offered to them by the Government departments destined to take care of their interests should continue in such a state in comparison to those abroad; and I hope that if you can find space for this letter, the influence of your paper may be the means of drawing the necessary attention to a somewhat neglected subject.—Yours, &c.,

G. W. B. ELPHINSTONE.

101, St. Martin's-lane, W.C., March 13, 1896.

A STANDARD ONE-VOLT CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In last week's article on "The Potentiometer," Mr. Fisher mentions some results he had obtained with nine specimens of a one-volt cell I submitted to him, and intimates that if they give equally good answers to time and high-temperature tests they are likely to be useful.

It may be worth while saying that I hope very soon to offer evidence on these and other points. Mr. Sewell, one of my students, and I have been working for 18 months to overcome the difficulties involved in making a practical standard volt, and we believe we may now offer it to the public with some confidence.—Yours, &c.,

W. HIBBERT.

14, Goldhurst-terrace East, N.W.,
March 17, 1896.

THE CLARK CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The extremely optimistic tone, with reference to the Clark cell, adopted by Mr. Fisher in his article on the Crompton Potentiometer which appeared on page 647 *et seq.* of your last issue, renders it advisable that a word of caution and warning be addressed to the users of these cells. It is no doubt comforting to hear, from one who can speak with the authority of experience, that such a useful piece of apparatus as the Clark cell is not the delicate fragile thing that so many of us once thought it. We should be careful, however, that the diffusion of this further knowledge is safeguarded, so as to prevent it becoming harmful knowledge. All that the writer of the article really urges is, that the treatment scheduled in his second paragraph is not permanently destructive to the cell.

One other remark may be made. The article is not quite accurate in stating that the Board of Trade adopted "The Clark cell as a standard of E.M.F.," or "Gave it the value of 1,434 Board of Trade volts at 15°C." The standard of E.M.F. is quite otherwise defined, and has no reference whatever to the Clark cell. It is possible that it might have been wiser policy with regard to the Clark cell had the Board of Trade refrained from adopting a "Specification"; or, perhaps, dropped the Clark cell altogether from consideration. That is a matter of opinion. It is a matter of fact, however, that Clark cells have been made in accordance with the Board of Trade specification, and have been found to give the stated E.M.F. with all the attainable accuracy. Not even the Board of Trade can embody in a specification all the manipulative skill and general laboratory experience required for the construction of a Clark cell. These are a necessary contribution by the maker of a cell to its efficiency and accuracy.—Yours, &c.,

"X."

THE SULLIVAN UNIVERSAL GALVANOMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Some four months back you kindly published a letter on the success of my galvanometer at sea. The enclosed two further reports on the subject may likewise be of interest, the one being from Mr. George Keith, director and engineer of the Cuba Submarine Cable Company, and the other from Mr. Raymond-Barker. Both letters are sent to you by permission:—

[Copy.]

Cuba Submarine Company, 58, Old Broad-street, E.C.,
March 6, 1896.

DEAR MR. SULLIVAN: I duly received your note, and have great pleasure in saying I formed a very high opinion of your patent galvanometer from what I saw of its performance on board the "Silvertown" and "Buccaneer" during the laying of the Cuban coast cables. It is practically unaffected by the ship's movement; very sensitive, beautifully deadbeat, and enables accurate tests to be rapidly taken in all weathers. I consider it is an invaluable instrument on board ship, and far superior to the ordinary marine galvanometer. Wishing it every success, I remain, yours very truly, (Signed) GEORGE KEITH.

Silvertown, London, E., February 24, 1896.

MY DEAR MR. SULLIVAN: With all the pleasure in the world I hasten to assure you, in answer to your recent letter, that my experience of your marine galvanometer during our recent Cuba Coast Cables Expedition (I being—in the absence of our chief electrician—in charge of the electrical department), fully confirms the good opinions I formed of this apparatus from my own previous tests at Silvertown. . . . . An excellent opportunity was afforded for judging the practical advantages attaching to your galvanometer on board ship in a heavy sea—for on the way out we had bad weather, and for days rolled from 30deg. to 40deg. breaking the record one day with 44deg.—not to speak of severe pitching. . . . The little "Buccaneer," as you are aware, although an excellent seagoing vessel, can be, and often is, extremely *lively*, but in her testing-room the Sullivan galvanometer again gave extreme satisfaction, the reports I received of its performance from our Messrs. G. H. Bailey and J. F. Cooto being quite enthusiastic.

With regard to my own experience (o.b. the "Silvertown") during our voyage out, and during the laying of five sections of cable off Cuba, I will not trouble you with details, or tabulated figures. . . I must, however, just mention one excellent feature of your instrument to which, as far as I am aware, sufficient attention has not been drawn; I allude to your galvanometer in its capacity of *time saver*—for it allows of observations being made *far* more rapidly than is possible with the old ironclad "marines," thus—as frequently happened during our recent trip—*shortening the time during which the ship had to hang on to cable.* . . . With your delightfully simple device, a good balance for rolling and pitching was very soon accomplished.—I remain, with kind regards, yours very sincerely,

E. RAYMOND-BARKER.

P.S.—There is one obvious factor in the success of your galvanometer which I have not pointed out, viz., its *constancy of zero*, not only with changes in the ship's course, but under the numerous outside magnetic disturbances common on board ship, which so affect the working of the old marine galvanometer, its thick ironclad protection notwithstanding.—E. R. B.

I also enclose for your own perusal a further report, recently received from another source, and which, as you will see, confirms the foregoing, but this I am not at liberty as yet to publish.—Yours, &c.,

H. W. SULLIVAN.

29, Ladbroke-square, W., March 18, 1896.

LEGAL INTELLIGENCE.

The Dolbear Patent for Hollow-Core Air Dielectric Cables.

On Wednesday, before the Judicial Committee of the Privy Council, present Lords Watson, Davey and Hobhouse, and Sir Richard Couch, the petition was heard of Amos Emerson Dolbear, and of the British Insulated Wire Company (Limited), in the matter of letters patent No. 1,368 of 1882 [for abstract see *The Electrician*, February 14, 1896, p. 504] granted the former in respect of the invention of certain improvements in electrical cables, and subsequently assigned by him to the Company. The petition prayed that the term of such letters patent, which is about to expire, might be extended by 14 years or such term as might be decided upon. Mr. Fletcher Moulton, Q.C., Mr. W. R. Bousfield, Q.C., M.P., and Mr. J. C. Graham supported the petition; the Attorney-General, Sir Richard Webster, Q.C., M.P., and Mr. H. Sutton appeared on behalf of the Crown; while Mr. C. A. Cripps, Q.C., M.P., Mr. R. Wallace, Q.C., and Mr. A. J. Walter represented the caveators, the Fowler-Waring Cables Company (Limited), the National Telephone Company (Limited), and the Western Electric Company, of Coleman-street, and New York.

Mr. FLETCHER MOULTON, in opening, after briefly referring to the terms of the petition stated that the rapidity with which they could charge and discharge an ordinary insulated cable limited the number of messages that could be sent. The matter of the insulator, therefore, was of great

Digitized by Google

importance. The patent which Prof. Dolbear took out in 1882 was for so constructing cables as to reduce to its smallest extent the surface contact between the internal conductor and the external covering. Prof. Dolbear thought they might support the wire inside the tube by means of a spirally-running string which would touch the sides of the tube and thus hold the wire centrally; by making the sheath hollow or tubular, so that the conductor would lie in it, touching only the bottom of the tube; or by placing some fibrous packing, with air spaces in it, between the conductor and the sheath. When the patent was taken out it was intended mainly for submarine cables, as the telegraph and telephone wires had not become so numerous as to necessitate their being laid underground. The cables, however, of the cable companies were laid, and naturally capitalists were unwilling to go to the expense of relaying them for the purpose of an experiment; and although Prof. Dolbear kept up both the English and the American patent which had been taken out, he was unable to get the thing taken up. At last, in 1892, he sold it to Mr. Atherton, an official of the British Insulated Wire Company, who subsequently purchased it of him for £1,000.

Lord WATSON: I understand that the Company wish the patent to be prolonged in order to remunerate themselves for their hitherto unsuccessful trading, as well as to remunerate the patentee.

Mr. FLETCHER MOULTON: Yes, my Lord. Continuing, he stated that though the patentee and Company had, up to the present, received very little remuneration, the value of the invention was now recognised, and the demand for air-space cables was greatly increasing. Counsel then went on to refer briefly to the opposition that was offered to the petition, and in conclusion to express a hope that, in view of the impossibility of getting any profit at an earlier date, and of the merits of the invention, their lordships would see their way to grant a prolongation.

Prof. A. E. DOLBEAR, the inventor, was then called. He stated that he was in England in 1882. There had been great trouble in connection with sending electric impulses for telephonic work. Cables, as they had been made up to that time, were so strongly absorbent of electrical impulses that it was impossible to use cables. When sending a signal or an electrical impulse along an ordinary cable the current had first to charge the dielectric, and then pass on; this affected the sending of telephonic impulses, because so much of the impulse was used in charging the cable. His attention was directed to this subject in connection with cables first by finding in England, in 1882, that there was great difficulty in doing telephonic work—in conveying telephonic currents to any considerable distance. It was in view of those considerations that he arrived at his invention; and, he added, a cable that would be useful for telephony would necessarily be useful for any other cable work. He applied the air-space principle; and to attain that he had some string which was wound, spirally, round the wire inside the tube. If they had a wire surrounded with gutta-percha as an insulator it would defeat the object of the air space. He laid great stress on the words in the specification: "The outer surface of the wire being in contact with nothing but the air filling the pipe," which formed the basis of the whole patent. None of the previous specifications alluded to by the objectors attained the results which his patent gave. So far as he knew the patent had never been used in connection with submarine cables; but within the last two or three years it had become to be generally adopted for telephonic cables. The witness then went on to detail the steps he took in 1882 to get his patent taken up in England, and to explain that it was not pushed in America because his partner lost his financial resources in litigation regarding other patents. Besides the deed of assignment of the patent to the British Insulated Wire Company, there was a recent agreement with that Company that if the present petition were successful he was to be given a quarter of the resulting benefit.

Cross-examined by Mr. Cripps: He did not know that his invention limited the tube to containing only one conductor. As a theory only was the principle of air isolation known before the date of the patent. When he was offered £10 for his patent he was glad to take it because it was £10 more than he expected to get then. The arrangement as to his receiving a quarter of the benefit of the present petition was come to in this month. His invention had been used in America, but he had had no benefit from it, and he had not taken legal proceedings for infringement owing to want of money.

Mr. GEORGE NISBETT, chief electrical engineer to the petitioning Company, stated that this Company had been making cables with a naked wire in an enclosed air space since 1892. They had a licence for making cables under the Felten-Guilleaume (otherwise Hardingham) patent, which was a contrivance for twisting wires in pairs. As compared with wire covered with gutta-percha the capacity of naked wire in an air space would be reduced by about a quarter. The Felten-Guilleaume patent was merely a convenient method of arriving at the end which the Dolbear patent pointed out as desirable. The reduction of capacity referred to was of enormous importance—it was the primary basis of all their calculations.

Lord DAVEY pointed out that although the Dolbear patent was acquired for £10, the petitioning Company had to pay 5 per cent. for the licence to work under the Hardingham patent, such payment to be not less than £10,000 in the first five years.

Continuing, WITNESS said he had had made specimens of cable according to Scott's, Pratt's and Dolbear's specifications, using similar wire in each case, and he found that the capacity of the three was ·33, ·7 and ·078 microfarads respectively per mile. He knew of no other cable which would give results so favourable as Dolbear's cable.

Cross-examined by Mr. Cripps: In the cable that his Company had been manufacturing the sheathing was not according to Dolbear's specifications; but, nevertheless, the cable itself was distinctly according to Dolbear. The Company had, since 1893, been manufacturing cable like the specimen handed in by the last witness, which was substantially like Dolbear's. They acquired Dolbear's patent in 1895. He knew the Fowler-Waring Company were manufacturing what was substantially the Dolbear cable; but no proceedings had been taken for infringement of the patent.

By the Attorney-General: The Company was manufacturing cable, in 1892, which consisted of wire wrapped round with paper, which acted as an insulator. It was true that Scott's patent pointed out the value of air spaces for insulating; but that was perfectly well known previously.

Lord WATSON stated that for 10 years from the date of the patent no attempt had been made to push the patent in England, and although, since 1893, cable like Dolbear's had been manufactured by the petitioners, it was at least doubtful as to whether that cable had been produced under Dolbear's or Hardingham's specifications. Those were two chief difficulties that had to be met.

Mr. FLETCHER MOULTON asserted that Hardingham's patent merely followed out Dolbear's patent, and as to the 10 years elapsing, he contended that until recently the demand for the cable had not arisen.

Mr. NISBETT was then further examined to show that the cable his Company was now manufacturing was practically in accordance with Dolbear's specifications.

Mr. S. Z. de FERRANTI, electrician and Director of the petitioning Company, stated that Dolbear's cable was of such great value because it allowed so much more to be transmitted in a given time than any other; its value was so great that it would be hardly possible, commercially, to use any other cable to lay underground. He had looked through the alleged anticipations of Dolbear's patent, but none of them would give as low conductive capacity as Dolbear's. In general his evidence corroborated the preceding evidence.

Cross-examined by the Attorney-General: He knew the cable which Messrs. Fowler and Waring were making, which had paper loosely wrapped round it, and which greatly resembled Dolbear's, but neither in that case nor any other had the Insulated Wire Company taken proceedings. As regarded Hardingham's patent, he believed that was an improvement in detail of Dolbear's, and the method was slightly cheaper.

Mr. EDWARD TRACY, secretary to the British Insulated Wire Company, gave some evidence, very briefly, as to accounts. On a sale of £5,000 worth of cable in 1895 there was a loss of £116.

Dr. HOPKINSON stated that the cable the Company were now manufacturing was substantially according to Dolbear's specifications. If cables were made according to specifications lodged previous to Dolbear's it would not be as useful as one made on Dolbear's lines.

Mr. FLETCHER-MOULTON, in reply to Lord Watson, informed the Committee that, beyond the evidence given by Prof. Dolbear, he had no explanation to give as to the delay in pushing the patent; and he could not carry the case further.

Lord WATSON then conferred with his colleagues, after which he announced the decision of the Committee. He stated that the patent was granted in March, 1882, and acquired by the petitioning Company in 1894, and in all that time no attempt had been made to push the patent. There had been no explanation of that delay; and the Committee were of opinion that the patent principally used by the petitioners was Hardingham's patent. In these circumstances they would advise Her Majesty not to grant the prayer of the petition, and that the caveators be allowed one set of costs.

The proceedings then terminated.

Clarke v. Julius Sax and Co.

Mr. Swinfen-Eady, Q.C., applied to Mr. Justice North in the Chancery Division for an injunction restraining the defendants from infringing the plaintiff's registered design for electric lamps. The learned counsel referred to the motion which had already been brought, in which his lordship held that the plaintiff's design was valid, but that the defendants had not infringed it. He contended that what the defendants had now done was to so exactly imitate the plaintiff's design that the two were hardly distinguishable.

Mr. VERNON SMITH, Q.C., for the defendants, contended that their lamps were no infringement.

His LORDSHIP, after hearing evidence, thought that this was a clear and palpable case of infringement, and granted an injunction restraining the defendants from using the lamps complained of or otherwise infringing the plaintiff's registered design.

Mr. VERNON SMITH asked if the defendants might be allowed to alter the lamps.

His LORDSHIP declined to accede to that application, and said that the injunction must be restraining the defendants from keeping the lamps complained of (which were placed in the Metropolitan Meat Market) without the leave of the plaintiffs.

Foote and Milne v. the Army and Navy Auxiliary Supply (Limited).

On Wednesday, in the Westminster County Court (London), the plaintiffs made a claim of £21. 6s. 1d. for electrical fittings and apparatus delivered to the defendants, who admitted receiving the goods, and paid about £5 into Court. The plaintiffs stated that the firm of Statter and Co. made arrangements with the defendants to carry out all their (the defendants') electrical installations. Statter and Co. joined the list of limited liability undertakings, and, like its predecessors, the Electrical Engineering Corporation, soon went into liquidation, the plaintiffs purchasing the present account with others from the Receiver. The fittings for the value of which the present action was brought, were left with the defendants on sale or return, and had not been returned. Mr. John Darch, surveyor of the electrical department of the Stores, stated that the arrangement with the Statter firm was that the goods should be left at the stores at their own risk, and everything except £5's worth

Digitized by Google

was returned to the plaintiffs' predecessors. An assistant in the same department said that Statter's people often came and took fittings away, but he could not say that they did not replace them. His Honour gave judgment for the plaintiffs for £8 beyond what was paid into Court, and he was of opinion, after going through the items, that two ordinary business men could have come to terms, instead of bringing the matter into Court.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d., abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations issued February 6th.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices :—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.), Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue Dr. Gore's book is now ready, price 10s. 6d. post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables. 30s., post free.

TENDERS INVITED.—The Shoreditch Vestry invite tenders for (*a*) high-speed engines, dynamos, switchboards, instruments, and street lamps; (*b*) pumps, steam and water mains, water tank, and cast-iron work; (*c*) motor transformers and starting switches; (*d*) battery of accumulators and stands. Specifications, with forms of tender, can be obtained from the 23rd inst. from the Consulting Engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, Westminster, S.W. Tenders must be sent in to Dr. H. Mansfield Robinson, Vestry Clerk, not later than 4 p.m. of Tuesday, April 14th. Some further particulars are given in our advertisement columns.

——— The Electric Light Committee of the Bedford Corporation invite tenders for the supply and erection of one 240 B.H.P. double-acting compound enclosed engine, and one 150-unit alternator with stationary armature. Tenders must be sent in to the Clerk to the Urban Sanitary Authority (Mr. T. S. Porter) by April 4th. Further particulars are given in our advertisement columns.

——— The Edinburgh Corporation require tenders for the wiring of the City Chambers. Tenders must be sent in to the Town Clerk, Mr. Thomas Hunter, W.S., by 10 a.m., on the 28th inst.

TENDERS INVITED.—The Corporation of Bradford invite tenders for batteries, surface condensing plant, cables, travelling crane and steam and exhaust pipes. Forms of tender and specifications may be obtained from the Electricity Office, and tenders, addressed to the Chairman of the Gas and Electricity Committee, must be delivered at the office of the Town Clerk (Mr. W. T. McGowen), Town Hall, Bradford, by the 26th inst. Further particulars appear in our advertisement columns.

——— The Municipal Council of Lima (Peru) invite tenders for the establishment and working of an electric lighting installation in the squares and streets of the city, with power to work the private service, under a contract for twenty years. A memorandum explaining the local conditions, &c., may be obtained at the Peruvian Legation, 13, Comeragh-road, West Kensington, London, W., and tenders will be received at the Legation up to the 1st June. Some further particulars will be found in our advertisement columns.

——— The Vestry of St. Pancras, London, require tenders for additional plant at the King's-road supply station, comprising engines, dynamos, connections, switchboard and other apparatus. Specifications, &c., can be obtained at the Electricity Department offices, 57, Pratt-street, N.W., and tenders must be sent to Mr. Albert E. Pycraft, chief clerk of the Department, by noon of Thursday, the 26th inst. Further particulars are given in our advertisement columns.

——— The Urban District Council of Wallasey require tenders for (*a*) steam alternators, switchboard and accessories, (*b*) high and low tension concentric cables, and (*c*) transformers. Copies of specification can be had of the engineer, Mr. J. H. Crowther, Gas and Water Works, Great Float, near Birkenhead. Tenders must be sent in to Mr. W. Danger, clerk to the Council, Public Offices, Egremont, Cheshire, by 4 p.m. of Monday, the 6th April. Our advertisement columns contain further particulars.

——— Tenders are invited for the supply of the necessary plant for the electric lighting of the County of Antrim Lunatic Asylum. Tenders to the Secretary of the Board of Control of Lunatic Asylums, Custom House, Dublin, by May 1st.

——— The Belgian State Railway authorities invite tenders for 180 dynamo brushes of various sizes, a quantity of mica, insulated copper wire, incandescent lamps, &c. Tenders to La Bourse, Brussels, by the 25th inst.

——— The Cardiff Corporation require tenders for supplying and fixing two dry-back marine or water tube boilers capable of evaporating about 6,000 lbs. of water per hour, and one 250 to 300 kilowatt direct-driven steam alternator. Specifications from the Borough Engineer, and tenders to be sent to the Town Clerk, by the 6th April.

TENDERS ACCEPTED.—The tender of Messrs. Johnson and Phillips has been accepted by the Tunbridge Wells Town Council for the supply of a Willans engine for the electricity works at £750.

APPOINTMENTS VACANT.—The Bolton Corporation invite applications for the appointment of borough electrical engineer. Salary £300 per annum. Applications must be sent in to Mr. R. G. Hinnell, town clerk, Town Hall, Bolton, by April 6th next. Further particulars appear in our advertisement columns.

——— The Vestry of St. John's, Hampstead, invite applications for the post of assistant electrical engineer, to work under the instructions of their chief engineer, at a salary of £2. 5s. per week. Some particulars will be found in our advertisement columns, and applications must be sent in to Mr. Arthur P. Johnson, clerk, Vestry Hall, Hampstead, by 10 a.m. of the 30th inst.

——— The Corporation of Ashton-under-Lyne invite applications for the position of consulting electrical engineer. Applications by the 23rd inst. to the Town Clerk.

——— A secretary is required for a provincial electric supply company who should have had experience in a similar position. Further particulars are given in our advertisement columns.

APPOINTMENT.—The Edinburgh Corporation has appointed Mr. F. A. Newington, the resident electrical engineer at the Millbank station of the Westminster Electric Supply Corporation, borough electrical engineer, in succession to Mr. E. W. Monkhouse.

BANKRUPTCY.—The examination of John H. Cox, electrical engineer, Kelly-street, Greenock, took place at the Sheriff Court, Greenock, on Friday last. The bankrupt stated that he commenced business in March, 1892, with a capital of £150. In August, 1895, he entered into partnership with Mr. T. D. Rorison, and the business had since been carried on under the firm of the Greenock and Glasgow Electric Company. He valued his half share in that business at £135, and he denied liability for the sum claimed by Mr. Rorison. His liabilities amounted to £945. 6s. 5d., and had been principally incurred in connection with experiments as to a

Digitized by Google

patent for the electro-plating of large surfaces, for which he had obtained provisional protection. The debt due to Messrs. Denny Brothers (£593. 15s. 5d.) was for wages and material advanced to him for the copper plating of a vessel. If the plating of that vessel had been successful he would receive between £40 and £50, but he had not included that in his assets, because its success had not been proved, and neither had he included the value of the provisional patent, as it had now lapsed, although he thought the value considerable. Mr. J. Nicoll was appointed trustee.

——— The following are the principal creditors in the failure of William Gray, jun., lately trading as an electrical engineer under the title of the Scottish Electrical Engineering Company, at Frederick-street, Edinburgh :—

B. Verity and Sons	£91	0	4
W. T. Glover and Co.	49	10	11
Dick, Kerr and Co.	40	0	0
General Electric Company	36	10	3
J. Gibb and Son	29	5	9
William McGeoch and Co.	27	15	8
Acme Gas Engine Company	21	0	0
Thomas Scott and Co.	17	4	7
T. B. Campbell and Sons	13	14	0

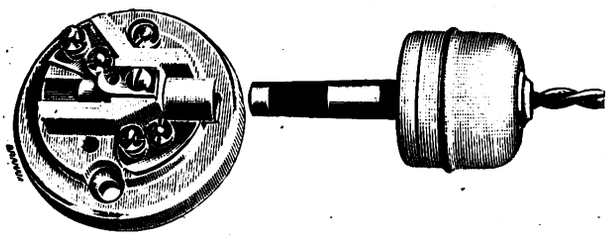
The liabilities amount to £2,700. 17s. 11d., and the assets to £2,291. 4s. 2d., subject to realisation.

——— Claims against the estate of George I. Reakes, lately trading as an electrical engineer, under the style of G. Reakes and Co., at Shrewsbury, must be sent in to the Official Receiver, Mr. T. Bullock, Shrewsbury, by the 30th inst.

Amendment of Patent.—Notice is given that Headland's Patent Electric Storage Battery Co. (Limited), have applied for leave to amend the specification of Letters Patent, No. 15,120, of 1892, granted to H. W. Headland, for "Improvements in or applicable to electrical accumulators."

Exports to South Africa.—Under the classification of electrical, the value of goods exported from this country to South Africa for the week ended March 7th was £1,385 : Cape Town, £744 ; Algoa Bay, £72 ; East London (cable), £551 ; Delgoa Bay, £18.

Side Contact Wall Plug.—We give particulars below of two types of wall plugs which are being placed upon the market by Messrs. Hodges and Todd, having been brought out by the Electrical Installation Company. In one (see illustration) the plug contact is inserted horizontally, in the other it is inserted vertically. In this type of wall plug it is impossible for the fuse wire in melting to fall across on the opposite pole and strike an arc or produce a short circuit. It is impossible to produce a short circuit by the insertion of the plug connector. A short circuit can only be made



intentionally, and then only with difficulty. One pole only is exposed. It is agreed that wall plugs should be of small size and neat appearance and as *flat as possible*. This pattern does not project from the wall more than 1¼in., and the plug connector can be inserted or withdrawn even with anything close against the socket. Being a side contact wall plug, it can be used behind bookcases and other articles of furniture. It can be used on skirting boards to great advantage, whereas ordinary wall plugs, owing to their projecting so far from the wall, are constantly in danger of being knocked and broken.

Lithanode Storage Cells.—The Lithanode Electric Storage Company (Limited) announce that, owing to increase of business, it has been found necessary to enlarge the works and to provide more adequate offices and show rooms. The new premises secured include offices, show rooms and laboratory in the Strand District, where arrangements have also been made for recharging and preparing portable batteries. A new price list of this Company's manufactures is now issued, and can be obtained on application.

High-voltage Fittings.—The Edison-Swan Company give notice that in order to meet the present requirements for fittings of a high insulation for high-voltage currents, they are now ready to supply, under Patent 18,162 of 1891, switches, cut-outs and holders with patent enamel liners. Samples of these switches, &c., can be seen at the head office in Queen-street, Cheapside, London, at the West-End branch in Parliament-street, and at any of the Company's provincial branches.

Arc Lamps and Accessories.—We have received from Mr. G. Braulik a copy of his catalogue of Messrs. Körting and Mathiesen's arc lamps and accessories, for which he is agent in this country. The catalogue gives particulars of various designs of these lamps, and some loose sheets give prices of carbons, measuring instruments, &c.

Catalogue.—A well arranged catalogue and price list of dynamos and electric motors for direct and alternating currents is just issued by the Electrical Company, of 122 and 124, Charing Cross-road, London, W.C. One of the conveniences of the list is that it is provided with a foredge index which divides the subject matter in a handy way. The tabulated matter relating to the company's various types of dynamos and motors is well arranged, and all required information can be obtained at a glance. The list is divided into thirteen sections, dealing with the various manufactures of the Company, including heavy machinery, instruments, arc and incandescent lamps, wires, cables, and accessories. The catalogue can be obtained as a whole, or, the sections being complete in themselves, any one section can be obtained separately. The binding and printing of the complete book, without being over-elaborate, are everything that could be desired, and the illustrations show the large variety of apparatus which is manufactured by the firm. An interesting feature is the use of the metric system of weights and measures throughout the catalogue.

Personal.—A farewell dinner was recently given at Charlton to Mr. Samuel Sudworth on the occasion of his departure from the firm of Messrs. Johnson and Phillips, where he has held the position of superintendent of the dynamo manufacturing department from the time the firm commenced the manufacture of that class of machinery. After so many years of association he leaves with the regret and goodwill of every one. He relinquishes the position he has held for so many years to take over the works managership of the Consolidated Telephone Construction and Manufacturing Company at Coventry.

——— The members of the staff of the British Insulated Wire Company (Limited), of Prescot, on Monday last gave a farewell dinner to Mr. H. M. Brigg, who is leaving England to take charge of important electric traction work in South Africa.

Electro-Harmonic Society.—A smoking concert takes place on Friday next, the 27th inst., at the St. James's Hall Restaurant (Banquet Room), Regent-street, W., at eight o'clock. As usual, an excellent programme has been provided.

Bohemian Concert.—Under the chairmanship of Mr. Frank Bailey, the staff of the City of London Electric Lighting Company will hold their fourth annual Bohemian Concert in the Pillar Hall of the Cannon Street Hotel, London, on Tuesday, the 31st inst., at 7:40 p.m. An interesting programme is provided.

Aberdeen.—For some time past the Harbour Board has been making investigations into the question of lighting the harbour electrically, and a deputation from the Board has recently visited the harbours at Liverpool and Manchester for the purpose of inspecting the electric lighting arrangements there. It has been decided to light the harbour electrically, and to take current from the Corporation mains.

Agricultural Hall, London.—At Tuesday's meeting of the London County Council the Theatres and Music Halls Committee notified the receipt of plans and specifications for additional electric lighting at the Royal Agricultural Hall, Islington. The additional lighting is to the ground floor and galleries, to the minor hall and King Edward's Hall, and to some of the offices adjoining. The committee recommended that the plans be approved, and this was agreed to, subject to certain conditions. We have many times referred to the singular absence of the electric light at this great building, where for many of the exhibitions it would be especially advantageous. Some portion of the building has lately been lighted electrically by arc lamps, and it would appear from the above that it is intended now to light the whole of the building, galleries and smaller halls by electricity. If sufficient current is available, the Hall authorities should be able to dispose of a large quantity to exhibitors whose stands are frequently very badly lighted at a time when the hall is thronged with visitors. Perhaps also some of our more enterprising electrical firms may now be disposed to rent space at the more popular exhibitions.

Battersea (London).—At the last meeting of the Vestry the Finance Committee recommended that the municipal buildings be wired and fitted up for the electric light ; but, after discussion, the matter was referred back.

Bolton.—At the meeting of the Gas and Electricity Committee on Friday last, it was decided to accept the resignation of the Borough Electrical Engineer, Mr. J. H. Rider, and to advertise for a successor. The receipts of the department for the past month amounted to £628, against £258 in the corresponding month last year, making a total of £2,583 for the 12 months. There is at present an equivalent of 9,378 8 c.p. lamps connected.

Digitized by Google

BRIDGEND.—The Town Council, at their meeting on Monday last, considered the proposal of Mr. J. C. Howell to purchase their Provisional Order, and to establish electricity works in the town. After discussion, the Council agreed to the proposal conditionally.

BRISTOL.—At the last meeting of the Electrical Committee several applications were received for the supply of electric current for power purposes, including one from the Docks Committee for the Bristol Granary, and the electrical engineer (Mr. H. Faraday Proctor) was instructed to prepare a report on the matter.

CAPE TELEGRAPHS.—According to the *African Review* there is a dearth of skilled telegraphists in the Cape and the Transvaal. Last year between 60 and 70 clerks were sent to the Cape and 40 others are now on the way. These were all engaged in England, contrary to the usual practice of the Cape Telegraph Department, which recruits on the spot.

CHURCH LIGHTING.—The Parish Church of St Alban's, Holborn (the old cure of the famous Mr. Maconachie), is to be wired for the electric light.

CIVIL SERVICE ESTIMATES.—The estimates now before the House of Commons provide for the enlargement of the Government Telegraph Factory at Holloway, for the installation of the electric light in the new band stand, and along the footpath between Marble Arch and Albert Gate in Hyde Park, and for continuing the Patent Office extension.

THE CRYSTAL PALACE HORSELESS CARRIAGE EXHIBITION.—Applications for space at the forthcoming exhibition should be sent to the Manager of the Crystal Palace Company, but any engineering and technical queries should be addressed to the Executive Officer (Mr. A. R. Sennett, A.M.I.C.E., M.I.E.E.) at the Palace.

COMMISSION OF SEWERS (LONDON).—The engineer, Mr. Ross, has just presented his annual report on the works executed by the Commission during the year. Referring to the question of electric lighting, the report states that the number of arc lamps in use is 485. As to the question of lighting the minor streets of the City by electric lamps under the contract with the City of London Company, Mr. Ross states that, as the experiments with incandescent lamps and with alternating-current arc lamps in Basinghall-street and Aldermanbury did not prove satisfactory, the Streets Committee recommended that further experiments with arc lamps should be made, with the view to determine the description of lamp to be employed. This recommendation was agreed to, and arrangements are now being made to light Watling-street, Bow-lane, Bread-street, Friday-street and Old Change by continuous and alternate-current lamps, partly on brackets fixed against the fronts of the business premises and partly by lamps suspended across the centres of the streets.

COVENTRY.—Mr. Robert Hammond, consulting engineer to the Corporation, has presented a report upon the recently erected electricity works, and calls attention to the immediate necessity for further extensions to meet the demand for current. The expenditure to date is £23,485. The report gives particulars of the 150-kilowatt plant which has already been put down. The number of lamps of the equivalent of 8 c.p. now connected is over 3,000, and about 600 are awaiting connection. The demand by next year is expected to reach a total of 6,000 8 c.p. lamps. The total capacity of the two sets of plant now erected, Mr. Hammond reports, would probably meet the actual demand even when the 6,000 lights are connected, but would leave no reserve, and it is in order to provide this reserve (the importance of which he points out) that he recommends the prompt erection of further plant, suggesting that a 200-kilowatt plant should be put down at an estimated cost, including cables, of £8,900.

EXHIBITION.—In order to make known in Russia the progress made in other countries in the construction of light railways and river and canal boats, and the means adopted for propulsion, the Russian Government has decided that a special section of the Nijni-Novgorod Exhibition to open in May next shall be set apart for such exhibits, and that foreigners shall be allowed to show. A special building is to be erected at the cost of the exhibitors, who will also have to pay the cost of transport, &c.

FOLKESTONE.—The Town Council are applying for a Provisional Order, and at the last meeting a letter was received from Mr. Hopkins, a director of the Hotel Metropole Company, asking if the Corporation intended to carry out the provisions of the Order, as, in the event of their not doing so, he would be willing to form a company for that purpose. The Hotel Company intended to light their premises electrically, and unless the Corporation moved in the matter, they would have to take steps to carry out the work themselves. A letter was also read from Mr. C. C. Wampach offering £500 for the transfer of the Order. Both communications were considered at a special meeting of the Council on Wednesday.

GLASGOW.—The New Family Home in St. Andrew's-street is lighted throughout by the electric light.

HAMMERSMITH (LONDON).—The Electric Light Committee recommend the Vestry to accept the tender of Messrs. S. Z. de Ferranti (Limited), for the supply of the necessary machinery and plant for their proposed electricity station, and they also propose to appoint Mr. A. H. Preece consulting engineer for the work.

HUDDERSFIELD.—On the recommendation of the Watch Committee the Town Council have decided to obtain tenders for the erection of a new electricity station.

INDIA.—*Indian Engineering* states that there are several schemes afloat for introducing electric light and power into Bengal, and that the project for Darjeeling has been accepted by the City Commissioners. At Calcutta it has been decided to light "Belvedere," the official residence of the Lieutenant-Governor of Bengal, in addition to the Alipore Gaol and the Seebpore College. The project for lighting a portion of the city is being actively taken up, but the acceptance of schemes is stated to depend upon a complete schedule being incorporated in the Lighting Act, steps for which are in progress.

JAPANESE TARIFFS.—Under the recently-revised Japanese tariff law, which will come into operation shortly, an impost is made upon telegraph or galvanised wire of 0·256 yen per 100 cattirs (equal to 600grm. of the metric system of weights or 1·32277lb. English avoirdupois).

LEAMINGTON.—A letter from the Midlands Electric Light and Power Company, offering to tender for the public lighing, has been referred by the Town Council to the Watching and Lighting Committee for report.

LECTURE.—A lecture on "Water Power and its Applications" was delivered by Prof. D. S. Capper at Toynbee Hall on Saturday last.

LEICESTER.—The report of the Gas and Electric Lighting Committee, presented at the last meeting of the Town Council, stated that the gross profit on the revenue account of the electricity department for the half-year ended December 31st last amounted to £580. After paying interest and allowing for sinking fund, &c., there was a deficiency of £195. 7s. 2d. In moving the adoption of the report, the Chairman of the Committee (Alderman Lennard) thought the accounts submitted, which were for the second half-year's working of the station, were entirely satisfactory. After a brief discussion the minutes were approved.

LONDON SCHOOL BOARD.—Current for lighting the eastern portion of the head offices of the School Board on the Victoria-embankment has been obtained from the Metropolitan Electric Supply Company, but the remaining portions have been lighted by current generated by the Board's own plant. The cost of working this plant for the year 1895 was £806, while the cost of current for the eastern portion for the first five months of the year came to only £70. The Board has, it is stated, decided to abandon the policy of employing its own generating plant, and to obtain the whole of its supply in future from the mains of the Metropolitan Company. It is estimated that, under the new arrangement, the six winter months will cost £318 and the six summer months about £70, or £388 for the year. Under the old system the cost was over £900.

MANCHESTER.—The Town Council have decided to increase the salary of Mr. C. H. Woodingham, the city electrical engineer, from £500 to £600 per annum, and the salaries of Messrs. W. R. Wright, A. A. Day and G. G. Bell (electricians in their employ) each to £200 per annum. In view of the recent experiences of Bolton, Edinburgh, Hull, and other towns the Council have adopted a wise step.

MIDDLESBOROUGH.—Messrs. R. Craggs and Son have decided to adopt electricity instead of steam for driving the smaller machinery at their new yard.

NEWCASTLE-UNDER-LYME.—Major Marindin held a Board of Trade inquiry on Tuesday last respecting the objections made by the Corporation to the application for a Provisional Order to authorise the construction of an electric tramway between Hanley and Newcastle. Mr. Milward, who appeared for the promoters, said the total length of the proposed tramway was under three miles. He understood that one of the objections was in consequence of communication with Silverdale and Chesterton not being included in the present scheme, but he offered, if the opposition were withdrawn, on behalf of the promoters to apply for powers to extend the lines to Silverdale and Chesterton. Circulars had been sent to 4,055 ratepayers; 2,809 were in favour of the scheme, and 453 against. The Town Clerk opposed the proposed scheme.

NEWMARKET.—A lengthy debate on the electric lighting question took place at the last meeting of the Council. The Newmarket Electric Lighting Company are applying for a Provisional Order, and, in response to a letter from the Board of Trade, the Council recently instructed its surveyor to prepare a report on the matter. This report states that for a capital expenditure of about £10,000 the Council could establish profitable electricity works in the district. The Council have decided to apply for a Provisional Order and to oppose the application of the Company.

Digitized by Google

PORTSMOUTH.—Electric motors are now used in the extensive range of stables belonging to the Corporation in Park-road for driving the chaff-cutting and other machinery.

SERVIA.—A concession has been granted to Maxi S. Antorijevitch, a Belgrade jeweller, for working a network of local railways intended to connect certain districts on the Danube with the existing railway main lines, and it is stated that the concessionaire is free to choose electricity or steam as the motive power.

SOUTHAMPTON.—The Town Council at their meeting on Wednesday discussed the report of the Works Committee, recommending the Corporation to purchase the undertaking of the Southampton Electric Light and Power Company, Limited, for £21,000, and that application be made to the Local Government Board for sanction to borrow £50,000 to complete the purchase and to carry out the necessary extensions. Mr. Lemon, the Chairman of the Committee, moved the adoption of the report, and pointed out the importance of the local authority having the electric lighting in their hands. Electricity was growing in favour, and he contended the Committee were more than justified in their decision to buy out the Company's undertaking. After a long discussion, the Council adopted the recommendations for the purchase of the undertaking, and also for the application for powers for borrowing £50,000 for purposes of extensions by 29 votes to 4. The Southampton Company was registered in April, 1888, and has a subscribed capital of £3,540 in £5 Ordinary shares, £250 in £5 Preference, and £5,000 in 5 per cent. debentures redeemable at par in 1901. A dividend of 2½ per cent. was paid on the Ordinary shares for 1894, and the net revenue for 1895 amounted to £1,166. The station is on the continuous current system, and supply was commenced in 1891.

SOUTH STAFFORDSHIRE TRAMWAY COMPANY.—This Company has applied to the Board of Trade for a further extension of time for the use of steam upon their tramways in the Wednesbury district until March, 1897. In making the application the Directors intimate that before the expiration of the extended term they hope to be in a position to introduce an improved system of traction. At a special meeting of the Wednesbury Town Council this week it was decided to consent to the Company's application.

TURKEY.—The *Revue d'Orient* states that it has been decided to reorganise the telegraphic service of the Ottoman Empire, commencing with the lines of Asia Minor, which will henceforth be divided into three principal sections. The Constantinople-Bagdad line will be extended to India, the Constantinople-Aleppo line to Egypt *viâ* Beyrouth, and the Constantinop'e-Castambol line will be connected with the Russian system *viâ* Trebizonde. The first section, which is the largest, stands in great need of repairs. The number of employés specially engaged in the superintendence of the lines is to be considerably increased.

WHITEHAVEN.—A lengthy report from Dr. Hopkinson on the present condition of the electricity works was discussed at the last meeting of the Town Council. The report recommended the enlargement of the present storage battery, and the provision of a new and more powerful battery. With such an addition the committee would be able to get along for some time without enlarging the present station building; but additional land would ultimately be required, preferably near the present station, for extension purposes. The recommendations were adopted.

YORK.—The Streets and Buildings Committee have now received Prof. Kennedy's report on the electric lighting of the city. He recommends the borrowing of £20,000 for the purpose.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

February 25, 1896.

4,174. J. A. SINCLAIR. London. Improvements in the method of fixing caps to incandescent electric lamps, and in joining the leading-in wires of such lamps to contact plates.

4,175. J. A. FISHER. Birmingham. The sparkless switch.

EASTBOURNE ELECTRIC LIGHT COMPANY (LIMITED.).—The ordinary general meeting of this Company was held at Eastbourne on Monday last. The Chairman, in moving the adoption of the report and accounts, referred to the position of the Company, and to the satisfactory progress that had been made during the past year. He concluded by moving that a dividend of 7½ per cent. per annum be declared, which was agreed to.

ROYAL ELECTRIC LIGHT COMPANY OF MONTREAL.—Coupons on the £154,000 Four and a-Half per Cent. Debenture loan of this Company will be paid on and after April 1st, by the Bank of Montreal, 22, Abchurch-lane, E.C. Coupons must be left three clear days for examination.

COMPANIES' MEETINGS AND REPORTS.

W. T. Henley's Telegraph Works Company (Limited).

The seventeenth ordinary general meeting of this Company was held at the offices, 27, Martin's-lane, Cannon-street, London, on Friday last, Mr. Sydney Gedge, M.P., presiding.

The SECRETARY (Mr. A. E. Salmon) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I have a very pleasant duty before me to-day. I cannot call it a task, because I have to call attention to and move the adoption of what I think you will all agree with me is a satisfactory report and balance sheet. We have in our past history had to meet when we were obliged to tell the shareholders that the dividend we were looking forward to was still in the future—at one time in the dim and distant future. That time has now passed, We began to pay with a 5 per cent. dividend; we then paid 6 per cent., and now we are going to ask you to adopt the recommendation of the Directors to pay 8 per cent., and that upon a statement of accounts as to which the only thing I am afraid of is a murmur of not unnatural dissatisfaction on your part because we are not paying 10 per cent. or 12 per cent. instead of 8 per cent. I hope, however, before I sit down, that I shall be able to satisfy you that it is in your own interests—and our interests are identical with yours—that we only propose to pay you 8 per cent. instead of more for the past year. In the first place I should like to call attention to the profit and loss account, and to show you how it contrasts with what was a very good profit and loss account last year. Last year we brought forward £5,187—I mean that in 1894 we brought forward £5,187 from 1893. At the end of 1894 we carried forward £8,624, being an increase of £3,437. At the commencement of last year we brought forward that £8,624, and we are now carrying forward £13,367—a very considerable increase over the other amount. We have also set apart £5,000 to reserve, and we have written off nearly twice as much as we did in the previous year for depreciation, the amount so written off being £1,964 instead of £1,000. We have also spent on maintenance of our works during the last year about twice as much as usual, so as to ensure their being in first rate condition. The volume of our sales has increased over those of the year before by nearly 47 per cent., and this has not been by any means through our having had any large submarine cable work bringing in a large profit, but by the steady growth of our business. There is only one thing not earned in the year—that is the final dividend on the shares of the International Cable Company—£1,600. 7s. 9d. I think that, if you remember, I told you last year we might not have to pay anything on that account, but that we might get a small return, and we have got more than we expected, £1,600. The charges on that account were all brought against profits at the time, and we are therefore now justified in bringing this amount into the profit that we have to deal with. You will see that we have now in hand to deal with £18,942. 16s. 11d. That is the balance of our profit earned, and if we add to that the £8,624 brought forward from the profits of the previous year it gives us a total of £27,567 to deal with. Then came the question for the Board, what was the best thing to do with the money. After full consideration we decided—and we hope you will approve our decision—that it was best to keep the strength of our Company up, and not to go on dividing to the last farthing, or anything like the last farthing, but to keep a good balance in hand for two purposes. The first purpose is to create a reserve fund, wherewith in any possible time of difficulty we may be enabled to equalise our dividends, and the second is to have working capital amply sufficient for our wants. This is an exceedingly good way of dealing with money in hand. Some people say it would be better left to fructify in the shareholders' pockets. I doubt very much whether, if we paid a larger dividend—say 12 instead of 8 per cent.—the other 4 per cent. would fructify in the shareholders' pockets; but in our hands it does fructify, because we are able to make our purchases on much more favourable terms with cash than we could do if we gave the Company's acceptances. If you will look to your balance sheet you will find on the credit side bills receivable in hand £4,985, but you will not find any bills payable on the other side, because we have had money in hand with which to make our purchases in cash for the most part. There are therefore no bills running against us, and I think that in the transactions of a Company like this that is a very good feature. After making provision for bad and doubtful debts we have in bills receivable and debtors a sum of about £45,000, and cash at bankers and in hand £15,000—or, together, over £60,000. If you look at the debit side of the balance sheet you will find that all we owe is £17,525, and what is due to us exceeds what we owe by £42,841. I hope you will approve our keeping in hand this money as we propose to do, in order that it may fructify and with a view to our being able permanently to pay you a good dividend in case of bad times, and to pay you at least 8 per cent. next year, tho' I hope we may find it prudent to pay more. No promise can now be made as to that, but we have already profit in hand which we carry forward, if you confirm what we propose, which will enable us, if we do not earn a penny this year, to pay you the interest on our debenture stock, the dividend on our Preference shares and 8 per cent. on our Ordinary shares. We should be able to make those payments with the amount we now propose carrying forward, and we could do so without touching the reserve fund. That I think is a very strong position for a company to be placed in. The next point to which I desire to call your attention is this—that we have a gross profit on trading of £36,967, and that has been earned at an expense, including Directors' fees, of £14,176, or about 38 per cent. of the gross profit. That amount includes the salaries of the engineer and of the Managing Director, the rent of offices, the maintenance of works, and the salaries of

Digitized by Google

clerks, as distinct from the wages paid to working men and artisans, both at North Woolwich and here, and all that we may call general expenses not chargeable against particular jobs. If you look at the balance-sheet you will find that we show an increase in capital of £30,000 and an increase in stock of £5,450. The bulk of that capital has gone to the enlargement and improvement of our works and machinery. You find among our assets debentures and shares held in other companies, £2,766. 5s. That money has been invested for the purpose of extending your business, and with great advantage. Of this amount £2,500 represents shares in one company which has paid us a dividend of 3 per cent. You will see among the liabilities an entry "reserve under cable repairing contract invested in the joint] names of trustees for the Company and the Crown agent for the colonies," £2,927. That is not brought into account but is stated as a fact. You will be glad to hear, although the price of all trust securities is so high that we have been unable to invest the money to make the return we hoped for in the way of accumulation, yet the value of all these stocks has risen so greatly that that £2,900 has increased about £300 more. Although we have not been able to accumulate quite so much interest as we had hoped to do, yet the rise in the price of the stocks has made up for the small amount we have put by; and I have moreover, the great pleasure of again reporting to you that that cable, like the Halifax and Bermuda cable, is still as perfect as it was on the day it was laid, and we have not had to pay a shilling for repairing it. That, I think, speaks well for us and the work we turn out. There is only one other subject to which I desire to refer. According to the terms on which our preference capital was issued, the holders of it have the option until July 2nd next of giving six months' notice to convert into ordinary share capital. It will be for the convenience of the Company if the holders of the Preference shares avail themselves of that option, because it is clear that for the simplifiation of the accounts and any future financial operations, it is better to have £130,000 of Ordinary stock of one description than two stocks. The time may came when our business may so extend that we may want more capital, and may wish to raise it by the issue of Preference stock. A second Preference stock is not put on the market on the same advantageous terms as a first Preference stock, and therefore, although £30,000 is but a small amount, we should have probably to pay a higher rate of dividend if we issued a second Preference stock for obtaining more capital than we should have to pay if we had the £130,000 behind and no Preference stock. If we get rid of this £30,000 of Preference shares, we may be able to issue other Preference stock at 5 per cent. instead of 7 per cent. I think, therefore, that our Preference shareholders will do wisely to exchange their Preference shares at par for our Ordinary shares. They will themselves gain in the benefit to the Company. I now propose:—

"*That the report and the balance sheet now presented to the meeting be and hereby is adopted.*"

Major-General GEORGE HUTCHINSON, C.B., C.S.I., seconded the resolution, which was carried unanimously, as was the resolution declaring the dividends of 5 per cent., free of income tax, on the Ordinary and 7 per cent. on the Preference shares.

Mr. JENKINS proposed the re-election of Mr. Gedge as a Director, which was seconded by the Hon. R. STEWART and carried.

In acknowledging the compliment, Mr. GEDGE thanked the Directors for the support they had accorded him in the conduct of the business, and to Mr. Sutton (the Managing Director), to whom it was impossible to pay too high a tribute for the manner in which he conducted their business. A strong word of praise was also due to Mr. Hatton, their manager at the works, for the way in which he had discharged his duties. Their thanks were due, in fact, to all their officers and the staff for the excellent way in which they performed their respective duties. They had been able to enter into new arrangements with Mr. Sutton and Mr. Hatton, whereby the services of those gentlemen were secured to the Company for a term of years, and their friends would participate, as they ought to do, liberally in the Company's good fortune.

Mr. NEWTON was re-elected as a Director, and the retiring auditors having been again appointed, a vote of thanks to the Chairman and Directors terminated the proceedings.

Birmingham Electric Supply Company (Limited).

The annual meeting of this Company was held on the 12th inst., at the offices, Dale End, Birmingham, Mr. H. Buckley presiding.

The CHAIRMAN, in moving the adoption of the report and accounts, said the Directors were thoroughly satisfied with the progress made during the past year. The issue of new shares to the amount of £50,000, authorised by an extraordinary general meeting, had been carried into effect, twice the amount required being applied for by shareholders. The premium was used for wiping the item for preliminary expenses out of the balance-sheet, and further sums had specifically been placed against the cost of Provisional Orders. The reserve had also been materially strengthened. The policy of reducing the charge for current which, of course, had materially affected their revenue at first, had been justified by the result. The loss in revenue had been overtaken by the increase in consumption, and the prospects for the current year, as shown by the returns for the first two months, were eminently satisfactory. Not only were they getting fresh customers, but their present customers were increasing their consumption. The report of the Birmingham Old Library showed that last year, when the establishment was lighted by electricity, the cost (including repairs and renewals of lamps) was £75. 9s. 9d., against £77. 3s. 9d., for gas in 1893. This result was attributed to the fact that the electric light was better distributed and could more readily be economised. The Birmingham Library was not the only concern that had had such an experience with the electric light. The supply of current for the district of Edgbaston was only available at the beginning of November, and was not available for the jewellers' quarter till January. This was caused by the non-delivery of the plant for the distributing stations, due to the destruction of the electrical engineering works at which it had been constructed. At the present time they had 20 miles of mains in the streets of the city, and there was a fairly steady increase both in the summer and in the winter consumption, while the increase in the number of lamps was quite steady.

A dividend of 4 per cent. was declared, and the retiring Directors, Mr. H. Buckley and Mr. F. W. V. Mitchell, were re-elected.

In reply to a question, the CHAIRMAN said that they were unable to declare an interim dividend because during one-half of the year their revenue was small as compared with that for the other half, but whether they would be able to do so in the future would depend largely upon the extent to which electric motors came into use in the city, as it was a day load they required.

Direct Spanish Telegraph Company (Limited).

The report and accounts of the Directors of this Company for the year ending December 31st last will be presented at the yearly general meeting of shareholders, held on Tuesday next, the 24th inst., at Winchester House, London, E.C., at 12 o'clock:—

The accounts show a balance to credit of revenue of £13,239. 12s. 9d. After providing for interest on and redemption of debentures, and adding £5,000 to the reserve fund, the balance of revenue amounts to £5,801 6s. 9d., and the Directors recommend the declaration of dividends for the past year of 10 per cent. on the Preference shares and 4 per cent., free of income-tax, on the Ordinary shares, absorbing £5,486. 4s. Half of this amount was distributed on October 1st as an interim dividend, £315 2s. 9d. is carried forward. The reserve fund now amounts to £28,498. 8s. 8d.

The traffic receipts show an increase of £4,571. 14s. 6d. as compared with the year 1894, and the ordinary working expenses are £238. 4s. 11d. in excess of those for the year 1894.

The Company's cables, and the land-lines in connection with them, have continued in good working order throughout the year. The report refers to the loss the Company has sustained by the death in June last, of Señor Don José Aparicio, who had been the highly-valued representative of the Company in Spain since its formation. Señor Don Vicente Coromina has been appointed his successor.

Mr. Edmund Etlinger and Mr. J. Denison Pender offer themselves for re-election as Directors, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

Sheffield Electric Light and Power Company (Limited).

The report of the Directors of this Company, to be submitted at the ordinary general meeting of shareholders, to be held on Monday next, the 23rd inst., at the Cutlers' Hall, Sheffield, at noon, states that there is a balance of profit for the year of £3,391. 9s. 4½d., to which must be added £531. 17s. 0d. from last account, making a total of £3,923 6s. 4½d.; and after deducting £1,119. 19s. 10d. for interest on Debentures, £220. 16s. 11d. proportion of formation expenses written off, and £750 transferred to depreciation fund, there remains a balance of £1,832. 9s. 7½.

The Directors recommend the payment of a dividend of 5 per cent. per annum out of this sum, which will absorb £1,744. 10s. 8d., and propose to carry forward the balance of £87. 18s. 11½d. The total sum now standing to the credit of depreciation fund is £2,000, and the whole of the machinery and plant is in excellent condition. In 1893 the gross revenue of the Company amounted to £3,555. 11s., in 1894 to £4,849. 9s. 4d., and in 1895 to £6,935. 4s. 1d.

During the year £16,426. 18s. 7½d. was expended upon machinery, mains, and other apparatus, and in order to provide the necessary capital for the further development of the Company's business, the Directors have decided to offer to the present shareholders 3,375 shares at a premium of 10s. per share.

Accompanying the report is a circular letter inviting subscriptions for 3,375 shares of £7 each. The nominal capital of the Company is £98,000 in £7 shares, and £25,000 Four and a-Half per Cent. Debentures, and the subscribed capital amounts to £41,875 plus the debenture issue.

MEMORANDA—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31⅜d. per oz. (March 19th). Consols (2¾ per cent.) 109⅜—109⅝ for money, 109¼—109⅜ for account; 2½ per cent. 105⅞—106⅛ (March 19th). Stock Exchange Settling Days: Consols, March 30th; Stocks and Shares Continuation Day, March 25th; Ticket Day, March 26th; Pay Day, March 27th; Mining Share Carry-over Day, March 24th.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment on April 14th next of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum, on the Preference shares of the Company, for the quarter ending 31st inst., and the usual interim dividend of 2s. 6d. per share on the Ordinary shares, free of income tax, in respect of profits for the quarter ended December 31st last. The transfer register will be closed from the 7th to 14th April inclusive.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—Notice is given that the thirteenth drawing for payment of the Five per Cent. Australian Government Subsidy Debentures (409 in number) will take place on April 1st next at the offices of the Company, at 11:30 a.m.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—The ninth ordinary general meeting of this Company will be held at noon on Tuesday, the 31st inst., at Winchester House, E.C. The transfer register is closed from the 21st to the 31st inst. inclusive.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1896, pages *318-346, &c., &c.*

COTTONWOOD WATER POWER AND ELECTRIC COMPANY (LIMITED).—This Company was registered on March 13th, with a nominal capital of £210,000, in 105,000 Preference and 105,000 Ordinary shares of £1 each, to enter into an agreement with John E. Condict to carry on in the territory of Utah (U.S.A.) and elsewhere the businesses of a power and electric supply company, to generate, accumulate, sell, supply and distribute power or energy, and to develop, accumulate, sell, supply and distribute electricity for lighting, heating and manufacturing purposes. The first subscribers are: F. Williams, Col. A. J. Filgate, H. R. Savory, R. A. Fairclough and J. Boustead (250 shares each); and E. A. King and Frank Stuttaford (with one share each). The first Directors are: J. Boustead, Col. A. J. Filgate, R. A. Fairclough, H. R. Savory and F. Williams.

J. S. LEACH AND COMPANY (LIMITED).—This Company was registered on March 11th, with a nominal capital of £10,000, in £1 shares, to acquire the business of a mechanical and electrical engineer, millwright, machinery manufacturer, &c., now carried on by Mr. E. W. Donovan under the style of "J. S. Leach and Company," at Harpurhey and Slaford. The first Directors are: E. W. Donovan (governing) and Harry Statham (managing).

LONDON ELECTRO-PLATING AND REFINING COMPANY (LIMITED).—This Company was registered on March 13th, with a nominal capital of £1,000, in £1 shares, to acquire the business carried on under the style of the London Electro-Plating and Refining Company, by Messrs. A. V. Pittar and A. Soden, and to carry on the business of electro-platers, electro-typers, enamellers and metal refiners. The first Directors are: Edgar W. Beckingsale, A. V. Pittar and A. Soden. Mr. A. V. Pittar is to act as Managing Director at a salary of £65 per annum and 15 per cent. of the net profits.

SILICON ELECTRIC LAMP SYNDICATE (LIMITED).—This Company was registered on March 16th with a nominal capital of £8,000 in £1 shares, to test, experiment and develop certain inventions connected with the manufacture of electrical lamps, for which letters patent have been granted to R. Langhans, A. Berrenberg and E. D. Chaplin (which are under an agreement of sale to the Langhans-Berrenberg-Chaplin Patents, Limited), to carry on the business of manufacturers of incandescent and other lamps, and of filaments, wires, bulbs, or other parts or requisites of such lamps, and to carry on the business of an electric light company, and electricians, mechanical engineers, suppliers of electricity and manufacturers of electrical apparatus. The subscribers, with one share each, are: H. L. Pilkington, P. J. Miller, Templer L. Down, A. F. da Costa, F. D. Summers, W. H. Smillie and J. G. Bristow. First Directors are: Hon. R. C. Parsons, A. A. Campbell Swinton and Capt. H. L. Pilkington.

BRITISH ELECTRIC TRACTION (PIONEER) COMPANY (LIMITED).—The statutory return to March 5th has just been filed. The nominal capital is £100,000 in £10 shares, of which 5,000 have been subscribed for. A call of £2 per share has been made.

LITHANODE ELECTRIC STORAGE COMPANY (LIMITED).—The statutory return to November 21st has been filed. The capital is £12,000, in £1 shares, and 7,007 of these have been taken up; 5,500 have been issued as fully paid, and the full amount has been called on the remainder.

LONDON ELECTRIC SUPPLY CORPORATION (LIMITED).—The annual return to May 23, 1895, was not filed until February 26th last. The nominal capital is £1,250,000, in 200,000 Ordinary and 50,000 Preference shares of £5 each. 110,000 of the former, and 48,050 of the latter, have been taken up, and the full amount called. £3,740 has been received in respect of 1,950 forfeited shares.

LONDON ELECTRIC WIRE COMPANY (LIMITED).—The annual return to February 11th has been filed. The capital is £50,000, in 5,000 Preference and 5,000 Ordinary shares of £5 each; 4,188 of the former and 4,597 of the latter have been taken up, and 3,860 shares of each class have been issued as fully paid. The full amount has been called on the remaining 28 Preference and 737 Ordinary.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to March 5th has been filed. The capital is £350,000, in 50,000 Ordinary, 10,000 First Preference, and 10,000 Second Preference shares of £5 each; 15,000 Ordinary, all the First Preference, and 2,500 Second Preference have been taken up, and 5,000 of the Ordinary have been issued as fully paid. The full amount has been called on the remainder.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The annual return to March 4th has been filed. The capital is £400,000, in £5 shares; 68,000 shares have been taken up, and the full amount called.

POOLING ARRANGEMENTS.—It is stated that an agreement has been entered into by the General Electric Company and the Westinghouse Electric and Manufacturing Company of the United States providing for the pooling of patents and dual control in the management of the business by a joint board of directors, the object of the arrangement being to save administration expense.

CITY NOTES.

APOSTOLOFF AUTOMATIC TELEPHONE PARENT SYNDICATE (LIMITED).—The statutory general meeting of the shareholders of this Company was held in private on Monday last.

BARCELONA TRAMWAYS COMPANY (LIMITED).—An extraordinary general meeting of the shareholders of this Company is to be held on Friday next at Winchester House, E.C., to confirm the resolutions increasing the capital of the Company from £150,000 to £300,000, the increase being required for the conversion of the Company's system from horse to electric.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended March 15th were £949, against £912 in the corresponding week of 1895, an increase of £37. The total receipts for the half-year amount to £10,786, against £10,823 for the corresponding period of 1895, a decrease of £37.

COTTONWOOD WATER POWER AND ELECTRIC POWER COMPANY (LIMITED).—A prospectus has been issued in London this week of the above Company, which is a concern formed to acquire works and conduct operations at Little Cottonwood Creek, near Salt Lake City, U.S.A. No powerful reason is assigned in the prospectus why capital should be sought in this country for this enterprise rather than in the United States, except that several more or less well-known names are associated with the conduct of the Company. The present application is for 70,000 Seven per Cent. Preference shares and 70,000 Ordinary shares, both of £1 each. The vendor receives £200,000 for his share in the transaction—£35,000 in fully-paid Preference shares, £35,000 in fully-paid Ordinary, and the balance of £130,000 in cash, or partly in cash and partly in securities of the Company. The list of applications closed yesterday (Thursday). The Board of Directors include Col. A. J. Filgate (Chairman of the Hove Electric Lighting Company), Mr. H. R. Savory (a Director of the Salt Lake and Ogden Company), and the consulting engineer is Mr. J. S. Raworth, of the Brush Company.

IMPERIAL TRAMWAYS COMPANY (LIMITED).—At the ordinary general meeting of this Company on Saturday last the Chairman (Mr. Geo. White), in referring to the condition of the tramways of the Dublin Southern Company, is reported to have said that the general power station was in a very advanced state, and the equipment of the lines, as well as the overhead construction, practically completed. The sub-stations were so well in hand that they could be used at any moment, and the whole of the cars, both motor and trailer, had been built; but the contractors had assured them that the main obstacle to the actual completion of the installation was the non-delivery of the alternators and transformers, which were being built by Armstrong, Mitchell and Co. It seemed annoying to be told that had this order been placed in America the machines would have been delivered and the line opened months since, and that it was simply the desire to encourage home manufacture which had resulted in this annoying and unlooked-for delay in the completion of the electrical equipment. Matters were now, however, in such a state that they might confidently look forward to the completion and opening of the line during next month. So far as those lines were concerned, which had been approved of by the Corporation and the Townships of Pembroke and Rathmines, they had made all arrangements to start the works the day their Bill passed through Parliament.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER COMPANY (LTD).—At an extraordinary general meeting of this Company on Wednesday, the resolutions to purchase the Snaefell Mountain Railway for £72,500, and to increase the capital of the Company to £175,000 by the creation of 25,000 new £1 Preference shares, were approved.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 15th inst. amounted to £1,095. The amount for the corresponding week last year was £975. Increase £120.

OXFORD ELECTRIC COMPANY (LIMITED).—This Company invites subscriptions at par for 1,414 shares of £5 each. The authorised capital of the Company is £100,000 in £5 shares, and 6,586 fully paid shares have already been issued. There is also £25,000 Five per Cent. Debentures. The Company commenced to supply electric current in the city of Oxford in June, 1892, and has recently declared a dividend of 3½ per cent. for the year 1895. Applications must be sent in to the London and County Banking Company, Oxford, by the 31st inst.

ROCKHAMPTON (QUEENSLAND) GAS AND COKE COMPANY (LIMITED).—The report of the Directors of this Company (which also owns the electricity works) for the half-year to December 31st last states that the consumption of gas for the period under review fell off 39 per cent., and this is partly attributed to the shrinkage resulting from the encroachment of the electric light. There was also a slight drop in the quantity of electricity supplied during the half-year. The Directors state that "strenuous care has been exercised to avoid a too rapid development of this section of the Company's operations, to avoid an unnecessary clashing with the gas interests." Several additional consumers have been added to the list, and the general expenses are, with the aid of a battery of accumulators about to be installed, likely to be considerably reduced, and the prospect for the current half-year looks encouraging.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended March 13th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,805.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended March 15th are £2,592, against £3,107 in the corresponding period of 1895 The November, 1895, receipts (estimated at £4,253) realised £4,288.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 932. [No. 22. Vol. XXXVI.] FRIDAY, MARCH 27, 1896. PRICE SIXPENCE.

NOTES.

In our correspondence columns will be found a remarkable communication from Prof. G. M. Minchin. It is needless to say that it relates to X-rays. Prof. Borgman, of St. Petersburg, was the first to announce in this country (see *The Electrician*, February 14th, p. 501) that Röntgen rays electrified bodies, Prof. Righi, of Bologna, following closely on his heels (see *The Electrician*, February 21st, p. 552); but whilst the former found *negative* the latter found *positive* electrification. To day this discrepancy is explained by Prof. Minchin's discovery that different bodies are differently charged by X-rays; some, such as iron, platinum and gold, being positively charged, others like sodium, magnesium, tin, lead and zinc being negatively electrified. As Prof. Minchin remarks, this phenomenon would seem to dispose of the projected electrified particle hypothesis. Perhaps the most curious observation made by Prof. Minchin is that X-rays, when they impinge upon a negative substance such as magnesium, do not merely add to any negative charge it may possess, but rearrange it, so to speak, until by addition or subtraction it amounts to the charge they would independently have given it. If this observation stands the test of time and repetition, the X-rays will have developed yet another puzzling property of exceeding interest.

We are reminded by a contribution from Mr. Fournier-d'Albe on the classification of physical experiments that the use of symbols as abbreviated expressions of magnitude and, qualitatively, of things in general is of very early date; and that probably the second-named use is even older than the first. The Chaldeans and Hindus were among the first to employ algebraic and trigonometrical symbols; and the sciences of alchemy and astrology were media for the invention of a host of qualitative symbols. Close and extended reasoning about magnitudes is practically impossible without symbols, as anyone would discover who should attempt to work out a series of mathematical operations without them; but it has not been so universally admitted that symbols are advantageous when dealing with concrete things or qualitative abstractions. Logicians have long used symbols to denote certain qualitative processes of reasoning; and Boole has devised an almost complete system of "logical calculus," whereby mental operations might always be carried on symbolically, as they are in mathematics.

It has more than once occurred in the history of the physical sciences, that a system of symbols which originated only for qualitative use has gradually developed into an indispensable system for quantitative work. This happened, for example, with the symbols for the chemical elements. At the time when these were merely abbreviations, representing indefinite amounts of certain substances, it would have been impossible to predict the enormous accession of usefulness which they would receive from the discovery of the laws of atomic combination. Just in the same way, we are inclined to believe there are latent possibilities in the ingenious symbology which Mr. E. E. Fournier-d'Albe has applied to the classification of physical experiments. That some such code is gradually being forced upon us by the increasing scientific output due to increasing scientific activity, is evident from the kindly way in which such code phrases as "$\theta\phi$ diagram," "**B-H** curve," &c., have been received. And as the ever-increasing bulk of scientific research swells to more and more unmanageable dimensions, the question of the universal adoption of some code similar to that proposed by Mr. Fournier-d'Albe wil persistently press for solution.

The economic law for current density of distribution mains and feeders has been written in a variety of forms according to the particular view taken, yet we think that Mr. James Whitcher's investigations now published are made from a fresh standpoint. In his working equation, derived from the differential equation, he states the current density in terms of a constant multiplied by a quantity under a radix in the usual form; but the annual cost of energy instead of being expressed per horse-power per annum is expressed as the cost of one kilowatt-hour in pence. This is a figure the value of which is more easily grasped than that of the larger quantity, and lends itself more readily to comparison with the published figures of electric supply stations. Mr. Whitcher proceeds to point out that this quantity is not the average or mean cost per kilowatt-hour, but that it is the cost of adding another kilowatt to the rate of output. He finds that it follows a law which may be expressed as the summation of the rates per cent. of interest, maintenance and depreciation charges chargeable to the conductor when laid, plus a constant charge depending upon the stand-bye and constant losses, which are proportional to the capacity of the plant. For most practical cases the cost of an additional kilowatt-hour appears to vary between 1d. and 2d.;

Digitized by Google

so that 1·5d. may be taken as a first approximation. Mr. WHITCHER, making certain assumptions based upon the ruling prices of cables as generally used, and averaging capital charges at 7 per cent., gives two practical equations for the maximum current density in high-pressure feeders and low-pressure distributors, both bare and insulated. It is interesting to note that the economic current density does not vary at the same rate as the load factor. It appears from these figures that the maximum current density for high-pressure constant current feeders varies from 800 to 500 amperes per square inch between the limits of 500 and 4,000 hours per annum. With high-pressure feeders, with load factors of from 0·01 to 0·3, the current density varies between 830 and 600 amperes per square inch, and with low-pressure feeders from 750 to 550. With low-pressure distribution circuits the variation is from 1,400 to 1,000, and with bare copper distribution mains from 900 to 700, for the same load factors. These figures are averages based over the whole of the systems to which they apply, and require modifying if some of the conductors are worked at different times from others. For example, if one pair of feeders is fully loaded when the rest of the mains are lightly loaded, then the density in the pair should be greater than that over the rest of the system, and the cost of an additional kilowatt-hour in them will probably work out at about ½d., because practically independent of the fixed charges, and probably of the labour charges also.

AMONG the remedies which have been adopted for vibration troubles at generating stations the three-crank engine has played an important part. As a practical solution of an annoying and pressing difficulty this form of engine has already proved a decided success. But, from a strictly scientific point of view, there still remain in every three-crank engine forces which are not continuously in equilibrium, and which must tend to produce vibration. Three equally-spaced cranks are only mathematically in equilibrium when they move around a common axis in one and the same plane, and when the forces acting on the crank pins are always parallel and constant in magnitude, or when some equivalent condition obtains. In a three-crank steam engine the conditions are not equivalent; the cranks are in different planes, the obliquity of the connecting rods (usually very short in high-speed engines) throws the forces considerably out of parallel, and the steam pressures are not constant, but vary, as shown on the indicator diagrams. Moreover, the auxiliary moving parts, such as the valve gear, supply additional unbalanced forces. A valuable Paper on "The Determination of the Forces which Produce Vibration with Three-crank Engines at High Speed" has been read by Mr. R. M. FERRIER, B.Sc., before the North-east Coast Institution of Engineers and Shipbuilders. The subject is treated particularly in relation to marine engines, and Mr. FERRIER'S Paper would have to be modified somewhat before it would square with electrical engineering practice. Nevertheless, it is a useful contribution to the subject. Marine engines receive a not inconsiderable fraction of their vibration from the propeller; electric light engines certainly receive none from continuous-current dynamos, though the periodic variation in the reaction of alternators may supply a certain amount of vibration-generating force. All electric light engines are fitted with flywheels, which are absent from marine engines, and it is indisputable that a flywheel, although not supplying a balancing force in the strict sense, does, by virtue of its great inertia, tend to prevent small unbalanced forces from setting up actual vibration of the engine.

How many members of the Institution of Electircal Engineers ever "mark, learn and inwardly digest" that modest financial statement which is annually sent them under the protection of a halfpenny wrapper. Those who may have inadvertently deposited this document in the waste-paper basket may be interested to learn that the total receipts of the Institution for the past year amounted to £4,533, and the current expenditure to only £2,641; the satisfactory balance being practically all carefully invested. The Institution now possesses in all the substantial sum of £10,543 in safe investments, and its building fund amounts to £3,500. The *Journal*, comparatively humble production though it be, nevertheless costs the Institution nearly £500 nett. The finances of the Institution do not indeed involve big figures, but they involve much trouble, and great credit is due to those in charge of them for having placed the Institution on a financially sound basis.

AT a recent meeting of the Royal Meteorological Society a Paper on "Turner's Representations of Lightning" was read by Mr. R. INWARD. The author showed the truth to Nature of TURNER'S lightning by comparing the great painter's flashes with photographs of actual flashes. We are quite in agreement with the author of this Paper in regarding the Turnerian wavy flash as being more "correct" than the orthodox zigzag display At the same time, and without wishing to appear to criticise such a master as TURNER, we cannot refrain from pointing out that what the camera reveals does not necessarily conform to the canons of good art, nor look natural when depicted on canvas. Mr. MUYBRIDGE'S photographs of animals in motion reveal their actual postures, but these would be ludicrous if introduced into a picture, say, of a steeplechase or of a busy street. In like manner one may appreciate Turnerian lightning from the electromagnetic-theory point of view; but, for all that, to the plain man it has none of the vividness of the zigzag conventional counterfeit.

Sir John Pender.—We learn on inquiry at Arlington-street that there is no foundation for the rumour that Sir John Pender suffered a relapse last evening.

Cable Interruptions :—	Date of Interruption.
Puerto Plata—Martinique	December 19, 1895
Aden—Zanzibar	March 16, 1896

Appointment Vacant.—The post of Assistant Professor of Applied Physics is vacant at the Heriott Watt College, Edinburgh. Applications must be made to the Principal at the College on or before April 2nd. Salary £125 per annum.

Erratum.—On page 678, column 1, line 41, of our issue last week, for "the first term in the expression $H + 4\pi I = B$ should become *but* an inconsiderable fraction" read "the first term in the expression $H + 4\pi I = B$ should become *not* an inconsiderable fraction."

Digitized by Google

The National Telephone Company's Payments to the State. The amounts received by the State during the past five financial years from the National Telephone Company are:—1890-91, £44,007; 1891-92, £50,403; 1892-93, £57,620; 1893-94, £65,443; 1894-95, £72,693—a total of £290,166.

New Edition.—We have received an early copy of the syllabus of Vol. I. of the new (third) edition of "Electric Lighting and Power Distribution," by Mr. W. Perren Maycock, M.I.E.E. The work will be in two volumes, the first of which is to be published by Messrs. Whittaker and Co. soon after Easter.

Iron and Steel Institute.—The autumn meeting of the Iron and Steel Institute will be held this year at Bilbao. For the service of members wishing to attend the meeting a P. and O. steamer will be detailed, and the vessel will be used as a floating hotel during the stay in Bilbao. Visits will be made to iron mines and iron and steel works in the neighbourhood.

Flywheel Accidents in America.—With reference to our reproduction of an article from an American contemporary, tracing the cause of the Albany accident to a compound-wound dynamo having motored, Mr. Mordey has pointed out to us that the explanation is only correct for the case of compound machines connected parallel at the brushes only—that if the brushes are properly connected as well as the terminals an accident cannot occur in the way described.

Traction Currents in Houses.—On Tuesday morning last week considerable damage was done to house wiring in the suburbs of Hamburg by the accidental switching on of the tramway current at 520 volts pressure on to the electric light mains. Several fires occurred in consequence of the short circuits produced in the fittings and in casings. Where fittings were adapted for gas and electric light the current burned through the gas-pipes and set the gas on fire.

Electric Motors in Workshops.—At a meeting of the Manchester Association of Engineers on Saturday, the 21st inst., Mr. Daniel Adamson read a Paper on "Electric Driving," in which he detailed his experience of electric motors for driving cranes and other machinery. Mr. Adams testified to the superior economy and convenience of this method of driving, which has been extensively used at Messrs. Daniel Adamson and Co.'s engineering works at Hyde.

Cost of American Power Stations.—In an article on "Electric Power Stations," in the current issue of *Cassier's Magazine*, Mr. C. J. Field gives the following figures as the average cost per kilowatt of a 5,000-kilowatt power station:—Steam plant, including engines, boilers, pumps, heaters, condensers, piping, &c., £17; electric plant, including generators, switchboards, cables, &c., £6; power station, building under average building conditions of good foundations and no rock excavation, including foundations, buildings, stack, &c., £3; sundries, £2. These make a total of £28 per kilowatt, exclusive of real estate.

Merchant Venturers' Technical College.—Mr. Arnold Philip, B.Sc., has been selected for appointment as Professor of Electrical Engineering and Applied Physics in this College, in place of Prof. W. Wilson, M.A., who will shortly vacate the chair in consequence of his appointment to the post of Principal of the Salford Municipal Technical School. Prof. Philip received his early training in the laboratories of the Royal College of Science, and subsequently studied electrical engineering at the City and Guilds of London Central Technical College. He at present holds the post of Assistant-Professor of Applied Physics and Electrical Engineering at the Heriot Watt College, Edinburgh.

Pacific Cable Schemes.—The Ottawa correspondent of *The Times*, under date March 24th, states that advices received by the steamer Warrimoo to the effect that the Hawaiian Government have refused the application of Mr. Audley Coote for exclusive landing rights on the Hawaiian Islands for the proposed Americo-Japanese cable. Mr. Coote assured the Hawaiian Government that capital had been secured in Japan with which to construct the line immediately. He asked to be delegated to represent Hawaii in concluding a contract with Japanese principals on the basis of a draft contract submitted. This proposal was also declined by the Hawaiian Government as being beyond their power.

Expiring Patents.—On Sunday next, the 29th inst., will expire patent No. 1,516 of 1882, granted to the Société Anonyme des Cables Électriques (Système Berthoud, Borel et Cie.) for "An Improved Manufacture of Material for Electrical Insulation." The invention relates to the "manufacture of material for electrical insulation, consisting of linseed oil converted into a solid elastic body by the application of heat, with or without admixture of colophonium."——On Friday next, the 3rd. prox., will expire patent No. 1,614 of 1882, granted to Edward Weston for "Improvements in Magnets or Dynamo Electric Machines." The claims are for (1) "An armature wound with two or more independent continuous conductors, the adjacent sections of which are connected to alternate segments of the commutator"; and (2) "a cylindrical or annular armature core having grooves or recesses for the reception of the coils, and two or more independent continuous conductors wound therein, in combination with a commutator to whose segments the said coils are alternately connected."——On Friday next, the 3rd prox., will also expire patent No. 1,619 of 1882, granted to Hiram S. Maxim for "Improvements in the Manufacture of Carbon Conductors for Electric Lamps and in Apparatus Therefor." The invention relates to a process for manufacturing carbon filaments from plastic carbonisable substances by means of a carbon press cylinder and a die of centrally perforated stationary block and adjustable plates or slides, arranged to vary the aperture through which the material is expelled.

Röntgeniana.—The following addendum to Lord Kelvin's letter, which appeared on p. 702 of our last issue, arrived too late for insertion:—

Dr. Macintyre, of Glasgow, tells me that he finds platino-cyanide of potassium better in respect to colour than the platino-cyanide of barium mentioned in Röntgen's original Paper. He finds, however, that both salts give satisfactory pictures, visible instantly to the eye. It is well understood, of course, that both in Röntgen's original work and in trials and developments of it by others, it is only for recording results that photographs are necessary. Dr. Macintyre has constructed an arrangement for use in the Royal Infirmary of Glasgow by which already in his own house he has examined bones of patients suffering from disease. A young friend of mine, not troubled with any illness, was allowed to see the bones of his own foot without taking his boot off.

——Mr. A. A. Campbell Swinton will give a lecture in the Governor's Hall of St. Thomas's Hospital on Tuesday next on X-rays. Tickets can be obtained at the hospital, and the proceeds of their sale will be devoted to the Special Appeal Fund.—An interesting Paper was read before the Falcon Works Engineering Society, on the 18th inst., by Mr. E. H. Cozens-Hardy (student of the Brush Company), on "Röntgen Rays," in which, besides illustrating the subject by numerous lantern slides of very high quality, taken by himself and Mr. L. Cumming, of Rugby School, including one of the bones of the foot of a mummy, he also showed that he had made a close study of the subject since its first appearance before the world, and far from confining himself to merely following in the path of others, his Paper bore evidence of considerable independent research. Amongst other interesting points, he drew attention to the fact that the bulb of the Crookes tube, although containing no carbon, blackens in a similar way to that of an incandescent lamp, with this interesting difference, that the blackening takes place only in front of the cathode disc; whereas, on the contrary, on that part of the bulb behind the cathode disc a gradual whitening of the glass goes on; the tube, moreover, during the time that it is excited becomes distinctly positively electrified behind the cathode disc, and negatively so in front. The author also drew attention to experiments he had made by means of photographing coins placed at different angles to the tube and at different distances from the plate, which, after careful measurements, demonstrated that the source of the rays was at the inclined anode disc of the Crookes tube. He also stated that he had discharged a gold leaf electroscope at about 6ft. distance by means of the Crookes tube, a wooden partition wall intervening. A candle flame was found to be quite transparent to X-rays, and a possible trace of double refraction was found with the use of a rhomb of calcite.—An interesting letter from Prof. G. M. Minchin will be found in our Correspondence columns.

ELECTROMAGNETIC THEORY.—LXXXIV.*

BY OLIVER HEAVISIDE.

(*Continued from page 578.*)

§ 336. The next thing to be done is to show how the Bessel solutions in general are generated by waves. This was done before in the case of a uniform cable, leading to Fourier series. We take a source at a point, and construct the double wave it generates, going to right and left. Then we add on, one after another, terms representing the reflected waves generated at the terminals by the incident first waves and their successors and overlappers. The complete set of waves, when in operational form, makes a geometric series, which, when summed, expresses the operational solution in condensed form. Conversion to series of normal functions then follows by the expansion theorem. So we prove that the series of waves and the series in terms of normal functions are equivalent.

To do this for the Bessel series is not a useless mathematical complication, but is of fundamental importance, both from the physical and the mathematical side. From the physical side because in Maxwell's theory all disturbances of electric or magnetic force are propagated at a speed v settled by the inductivity and permittivity, which property is not interfered with by the simultaneous existence of conductivity (electric or magnetic). All solutions involving change are, therefore, ultimately of wave nature. This is also true when, by artificial restrictions, we make v be infinite. In such limiting cases we do not see any succession of waves in time, for they are made simultaneous, but there is no essential difference in the principle. The waves are there, all the same. Also, from the mathematical side, the question is important in casting light upon the connection between the two kinds of Bessel formulæ, the convergent and the divergent.

The wave analysis and synthesis is nearly as easily done for the Bessel waves of m^{th} order as for the zeroth, and is made plainer by the extension. Therefore, let

$$-\frac{dV}{dx}=\frac{Z}{x^n}C, \qquad -\frac{dC}{dx}=Yx^nV, \tag{1}$$

be the circuital connections of voltage and current, Y and Z being preferentially $K+Sp$ and $R+Lp$, so that the resistance and inductance per unit length of circuit vary as x^{-n}, and the leakage and permittance as x^n. The characteristic of V is

$$\frac{1}{x^n}\frac{d}{dx}x^n\frac{dV}{dx}=q^2V, \quad \text{or} \quad \frac{d^2V}{dx^2}+\frac{n}{x}\frac{dV}{dx}=q^2V, \tag{2}$$

where $q^2=YZ$.

This is the theory of the propagation of plane waves in a medium whose specific properties vary as the n^{th} or $-n^{\text{th}}$ power of the distance from a fixed plane; or of cylindrical waves when the variation is as the $(n-1)^{\text{th}}$ power, and so on to other dimensions. But n is not restricted to be an integer; it may be fractional if we like.

The first step is to find the wave operators. Let

$$H_m(qx)=\left(\frac{2}{\pi qx}\right)^{\frac{1}{2}}\epsilon^{qx}\left\{1+\frac{1^2-4m^2}{\lfloor 1\ 8qx}+\frac{(1^2-4m^2)(3^2-4m^2)}{\lfloor 2\ (8qx)^2}+\dots\right\}, \tag{3}$$

$$K_m(qx)=\left(\frac{2}{\pi qx}\right)^{\frac{1}{2}}\epsilon^{-qx}\left\{1-\frac{1^2-4m^2}{\lfloor 1\ 8qx}+\frac{(1^2-4m^2)(3^2-4m^2)}{\lfloor 2\ (8qx)^2}-\dots\right\}, \tag{4}$$

These are to define the functions H and K. It may be readily tested that $x^{-m}H_m(qx)$ and $x^{-m}K_m(qx)$ satisfy the characteristic (2), provided $n=1+2m$, or $m=\frac{1}{2}(n-1)$.

Now H and K are divergent series, that is, when qx is numerical. They are, nevertheless, actually the fundamental Bessel formulæ, because they are the wave generators. It is not difficult to see this. Suppose there is no waste of energy by resistance. Then $q=p/v$, and ϵ^{qx} is a mere translation operator, turning t to $t+x/v$ in any time function on which it works. Similarly ϵ^{-qx} turns t to $t-x/v$. Therefore, by § 276, the H operator belongs to an inward wave, and the K operator to an outward wave, if there is nothing else to interfere with this property. Now, in the case of a homogeneous medium $n=0$, and $m=-\frac{1}{2}$. Then H is simply proportional to ϵ^{qx} and K to ϵ^{-qx}, indicating propagation at constant speed without distortion. In other cases, H is $\epsilon^{qx}F$, and K is $\epsilon^{-qx}G$, where F, G are as in (3). The translation is still done by the exponential operators, but the operand is altered first by F or G. So these operators do the distortion, or deformation of the waves.

When there is resistance, q is not p/v. But the exponential operators may still be reduced to $\epsilon^{px/v}f$ and $\epsilon^{-px/v}g$, when f and g are other operators also concerned in producing distortion. Thus, from the fundamental fact that disturbances travel at speed v, the forms of H and K prove that they are the wave operators, H for an inward, and K for an outward wave. If this general reasoning is not convincing, I may add that the algebrisation of (3), (4) with an operand added is quite easily effected in various simple cases (and the extension to the general case is only a matter of complication) with the results as above described. Some cases will be given in Chap. VII.

Having settled this point, use H and K to show the primary waves generated by a source. Let there be a source h at y. Then

$$V_1=\frac{\pi}{4}Zh\frac{H_{mx}}{x^m}\frac{K_{my}}{y^m}, \qquad V_2=\frac{\pi}{4}Zh\frac{H_{my}}{y^m}\frac{K_{mx}}{x^m}, \tag{5}$$

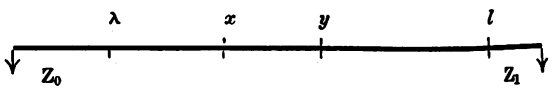
show the waves, V_1 to the left of y, and V_2 to the right. To prove this, note first that the proper operators containing x are used for the waves. Next, that $V_1=V_2$ at y. Thirdly, that $C_2-C_1=h$ at y. The last is done by the conjugate property of the H, K functions, which is

$$(HK'-H'K)_x=-\frac{4}{\pi x}, \tag{6}$$

if the accent means differentiation to x.

In (5) the operand is h, which may be any function of the time, but if we take it to be constant, beginning at the moment $t=0$, then V_1 and V_2 represent waves of V starting from y at that moment, and travelling to right and left at speed v.

§ 337. If there are no terminal impositions—that is, if the characteristic is valid (except at the source) all the way from $x=0$ to ∞, the V_2 wave goes on to infinity. But the V_1 wave, when it reaches the origin, generates a reflected wave, which also travels out to infinity. There are no more waves than these. But should there be a boundary on the right of y, say at l, both the outward waves, primary and secondary,



generate reflected waves there, and both these inward waves generate outward waves when they reach the origin, and so on for ever. It is the same when the origin is not in question, but the place of inner reflection is at $x=\lambda$, on the left of x and y. It is now easy to construct the wave series.

Let $x=\lambda$ and l be the boundaries, and the point x where V is wanted be on the left side of the source h at y. The first wave is

$$v_1=\frac{\pi}{4}Zh\frac{K_{my}}{y^m}\frac{H_{mx}}{x^m}, \tag{7}$$

by the first of (5). Put $x=\lambda$ to produce its value at λ. Multiply by a reflection coefficient, say a', to produce the value of the reflected wave at the same place. Then multiply by $(x^{-m}K_{mx})/(\lambda^{-m}K_{m\lambda})$ to express the reflected wave at any point, because this operator is 1 at λ, and has the right x function in it. The result is

$$v_2=\frac{\pi}{4}Zh\frac{K_{my}}{y^m}\left(a'\frac{H_{m\lambda}}{K_{m\lambda}}\right)\frac{K_{mx}}{x^m}=\frac{\pi}{4}Zh\frac{K_{my}}{y^m}a_1\frac{K_{mx}}{x^m}, \tag{8}$$

if a_1 is the operator in the brackets.

Put $x=l$ to give the value of v_2 at l. Then multiply by a reflection coefficient, say b', to give the value at the same place of the third (inward wave) generated by v_2. Finally, multiply by $(x^{-m}H_{mx})/(l^{-m}H_{ml})$ to produce the complete third wave anywhere. The result is

$$v_3=v_1\left(a'\frac{H_{m\lambda}}{K_{m\lambda}}\right)\left(b'\frac{K_{ml}}{H_{ml}}\right)=v_1a_1b_1, \tag{9}$$

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

if b_1 is the operator in the second brackets. After this, it is the same over and over again. Thus,

$$v_4 = v_2 a_1 b_1, \quad v_5 = v_3 a_1 b_1, \quad v_6 = v_4 a_1 b_1, \quad \&c. \tag{10}$$

The sum of all these waves is

$$\Sigma v = \frac{v_1 + v_2}{1 - a_1 b_1}, \tag{11}$$

which expresses V at x (less than y), so far as it arises from v_1.

But there is also the initial wave to the right to be considered. It does nothing at x itself directly, but only by reflection at l. Initially the primary wave is the V_2 in (5). Put $x = l$, and multiply by $b'(x^{-m}H_{mx})/(l^{-m}H_{ml})$, to produce the first inward reflected wave, say w_1, which can act at x. It is

$$w_1 = \frac{\pi}{4} Zh \frac{H_{my}}{y^m} b_1 \frac{H_{mx}}{x^m}. \tag{12}$$

After this it is to be treated in the same way as v_1 was, for both v_1 and w_1 are inward waves. Therefore

$$w_2 = \frac{\pi}{4} Zh \frac{H_{my}}{y^m} b_1 a_1 \frac{K_{mx}}{x^m} \tag{12A}$$

is the next outward wave, and the rest are

$$w_3 = w_1 a_1 b_1, \quad w_4 = w_2 a_1 b_1, \quad w_5 = w_3 a_1 b_1, \quad \&c., \tag{13}$$

Consequently the sum of the w waves is

$$\Sigma w = \frac{w_1 + w_2}{1 - a_1 b_1}, \tag{14}$$

and the complete V_1 at x is $\Sigma v + \Sigma w$; that is

$$V_1 = \frac{\frac{1}{4}\pi Zh}{1 - a_1 b_1} \left(\frac{H_{mx}}{x^m} + a_1 \frac{K_{mx}}{x^m} \right) \left(\frac{K_{my}}{y^m} + b_1 \frac{H_{my}}{y^m} \right). \tag{15}$$

It only remains to find a_1 and b_1, or a' and b', the reflection coefficients. Let $V = Z_1 C$ at l, and consider any outward wave and the reflected wave superposed. They are represented by

$$\frac{K_{mx}}{x^m} + b_1 \frac{H_{mx}}{x^m}, \tag{16}$$

multiplied by a factor not containing x. The corresponding currents are

$$\frac{x^{m+1} q}{Z} \left(K_{m+1,x} - b_1 H_{m+1,x} \right), \tag{17}$$

by the first of (1), and using these properties of the functions,

$$\frac{1}{q} \frac{d}{dx} \frac{H_m}{x^m} = \frac{H_{m+1}}{x^m}, \quad \frac{1}{q} \frac{d}{dx} \frac{K_m}{x^m} = -\frac{K_{m+1}}{x^m}, \tag{18}$$

which are easily verified by the definition of H and K above. The ratio of (16) to (17) is therefore Z_1 when $x = l$. So

$$Z_1 = \frac{K_{ml} + b_1 H_{ml}}{(l^n q/Z)(K_{m+1} - b_1 H_{m+1})}, \tag{19}$$

and therefore

$$b_1 = \frac{-K_{ml} + BK_{m+1,l}}{H_{ml} + BH_{m+1,l}}, \quad \text{if} \quad B = \frac{l^n Z_1 q}{Z}. \tag{20}$$

In a similar manner, let $V = -Z_0 C$ be the condition at the other boundary λ, then we shall find by the proper change of symbols that

$$a_1 = \frac{-H_{m\lambda} + AH_{m+1,\lambda}}{K_{m\lambda} + AK_{m+1,\lambda}}, \quad \text{if} \quad A = \frac{\lambda^n Z_0 q}{Z}. \tag{21}$$

We may therefore write (15) symmetrically thus:—

$$V_1 = \frac{\pi Zh}{4x^m y^m} \frac{(H_{mx} + aK_{mx})(H_{my} + bK_{my})}{b - a}, \tag{22}$$

where a stands for a_1 as in (21), and b for the reciprocal of b_1 in (20), so that a is derived from b by turning l to λ and Z_1 to $-Z_0$. We have only to interchange x and y to obtain V_2 on the right side of the source, and the results are explicit in terms of the terminal resistance operators. They are derived entirely from the initial waves from the source, by the addition of the reflected waves. The divergent series are therefore essential to a proper understanding of the matter.

§ 338. Now consider a radically different way of viewing the subject. Besides the divergent series there are convergent series satisfying the characteristic. Thus $x^{-m} I_{mx}$ and $x^{-m} I_{-mx}$ are convergent solutions of the characteristic (2), if

$$I_m(qx) = \frac{(\frac{1}{2}qx)^m}{\underline{|0}\,\underline{|m}} + \frac{(\frac{1}{2}qx)^{m+2}}{\underline{|1}\,\underline{|m+1}} + \frac{(\frac{1}{2}qx)^{m+4}}{\underline{|2}\,\underline{|m+2}} + \ldots, \tag{23}$$

and I_{-mx} or $I_{-m}(qx)$ is got by turning m to $-m$. These I functions are always finite at the origin when m is positive or zero, and infinite when m is negative. It follows that

$$V_1 = \frac{I_{mx} + rI_{-mx}}{x^m} A_1, \quad V_2 = \frac{I_{mx} + sI_{-mx}}{x^m} B_1, \tag{24}$$

are general solutions, and represent V on left and right of a source h provided r, s, A_1 and B_1 are properly found.

First, $V_1 = V_2$ at y, the place of the source h, makes

$$B_1 = \frac{I_{my} + rI_{-my}}{I_{my} + sI_{-my}} A_1, \tag{25}$$

so B_1 is eliminated. Next, A_1 is to be found by $C_2 - C_1 = h$ at y. Now the C's corresponding to (24) are

$$C_1 = -\frac{q}{Z} x^{m+1} (I_{m+1,x} + rI_{-m-1,x}) A_1,$$

$$C_2 = -\frac{q}{Z} x^{m+1} (I_{m+1,x} + sI_{-m-1,x}) B_1, \tag{26}$$

because

$$\frac{1}{q} \frac{d}{dx} \frac{I_m}{x^m} = \frac{I_{m+1}}{x^m}, \quad \frac{1}{q} \frac{d}{dx} \frac{I_{-m}}{x^m} = \frac{I_{-m-1}}{x^m}, \tag{27}$$

as may be quickly tested by the series (23). So, applying the h condition just mentioned, we find

$$A_1 = \frac{hZ(I_m + sI_{-m})}{qy^{m+1}(r-s)(I_m I_{-m-1} - I_{-m} I_{m+1})} \tag{28}$$

at the point y. In the denominator a conjugate property is involved of voltage and current, in the manner of § 331, and the value of the quantity in the second brackets in the denominator is easily seen to be $x^{-1} \times$ constant. To find the constant, use the series (23), writing down the first terms of I_m, I_{-m-1}, &c.; and pick out the terms involving x^{-1}. There is only one. The result is

$$I_m I_{-m-1} - I_{-m} I_{m+1} = \frac{2}{qx\,\underline{|m}\,\underline{|-m-1}} = -\frac{2}{\pi qx} \sin m\pi, \tag{29}$$

because

$$\underline{|-m} = -\underline{m}\,\underline{|-m-1}, \quad \text{and} \quad \underline{|m}\,\underline{|-m} = \frac{m\pi}{\sin m\pi} \tag{30}$$

are elementary properties of the $\underline{|m}$ function, which we shall come across again in Chapter VII., to be there proved. Thus

$$A_1 = \frac{\frac{1}{2}\pi Zh}{y^m} \cdot \frac{I_{my} + sI_{-my}}{(s-r)\sin m\pi}, \tag{31}$$

and therefore, finally,

$$V_1 = \tfrac{1}{2}\pi Zh \frac{(I_{mx} + rI_{-mx})(I_{my} + sI_{-my})}{x^m y^m (s-r)\sin m\pi}, \tag{32}$$

in a symmetrical form, is another way of expressing V_1. If we determine s and r by the same terminal conditions as before, namely $V = Z_1 C$ at l, and $V = -Z_0 C$ at λ, we find

$$s = -\frac{I_{ml} + BI_{m+1,l}}{I_{-ml} + BI_{-m-1,l}}, \quad r = \frac{-I_{m\lambda} + AI_{m+1,\lambda}}{I_{-m\lambda} - AI_{-m-1,\lambda}}; \tag{33}$$

where A and B are as before, (20) and (21) above. So now the solution is, like the old one, explicit in terms of the terminal operators.

§ 339. We have thus, in (22) and (32), obtained two entirely different forms of solution of the same problem. In one way we built it up with the primary waves and their reflections—and it is certainly right (barring possible working errors). The other way ignores waves altogether, or indeed any sort of elementary component solutions, but is entirely operational, using formulæ which are convergent, when numerical. But the form (32) may be expanded by the expansion theorem into a series of normal functions of the subsiding or vibrating kind. We may therefore for the present regard (32) as representing this normal expansion, in the same way as we may regard (22) as representing the series of waves, for every wave given in operational form may be algebrised if we like. We

Digitized by Google

therefore prove the strict equivalence of the series of normal solutions and the series of waves, arising out of (32) and (22) respectively.

But, besides that, we may regard the investigations algebraically and numerically. For q may be a positive constant, namely, when $Z=R$ and $Y=K$. It is then the steady state due to h that is in question throughout, which is instantly assumed when h varies, because the speed v is infinite, and there are no time differentiations concerned in the various operators, which become constants or functions of x. So we prove the numerical equivalence of (22) and (32), when qx is positive number, apart from their equivalence as operational formulæ. What are then the relations between the divergent functions H, K and the convergent functions I_m and I_{-m}? They are involved in (22) and (32) of course, but it is not clear at first how they are to be exhibited. We must either rearrange (32) to show identically the same form as (22), or else the other way. But a trial with the sum and difference of I_m and I_{-m} used in (22) shows the way. Thus, keeping entirely to (22) at present, let

$$H_{mx}=I_{mx}+I_{-mx}, \qquad K_{mx}=\frac{I_{-mx}-I_{mx}}{\sin m\pi}. \tag{34}$$

These are merely to define H and K, without present reference to the former meanings. Then (32) becomes

$$V_1=\frac{\frac{1}{2}\pi Zh}{x^n y^m(s-r)\sin m\pi}\{\tfrac{1}{2}(1+r)H_{mx}+\tfrac{1}{2}(r-1)\sin m\pi\, K_{mx}\} \times\{\tfrac{1}{2}(1+s)H_{my}+\tfrac{1}{2}(s-1)\sin m\pi\, K_{my}\}, \tag{35}$$

which is expressible as

$$V_1=\frac{\frac{1}{2}\pi Zh}{x^n y^m}\frac{(H_{mx}+aK_{mx})(H_{my}+bK_{my})}{(s-r)\dfrac{4\sin m\pi}{(1+r)(1+s)}}, \tag{36}$$

if

$$a=\frac{r-1}{r+1}\sin m\pi, \qquad b=\frac{s-1}{s+1}\sin m\pi, \tag{37}$$

in the numerator of (36). Here r and s are given in (33) according to which (37) become

$$a=\frac{-H_{m\lambda}+AH_{m+1,\lambda}}{K_{m\lambda}+AK_{m+1,\lambda}}, \qquad b=-\frac{H_{ml}+BH_{m+1,l}}{K_{ml}-BK_{m+1,l}}. \tag{38}$$

Next, there is the denominator in (36). Putting it in terms of a and b in (37), we find its value is $2(b-a)$. So

$$V_1=\frac{\frac{1}{4}\pi Zh}{x^m y^m}\frac{(H_{mx}+aK_{mx})(H_{my}+bK_{my})}{b-a}. \tag{39}$$

This being merely a modification of (32), compare it with (22). They are identical; for the present a, b given by (38) are identical with the a, b of the divergent investigation, viz., a_1 in (21) and the reciprocal of b_1 in (20). But in (22), H and K are defined by the divergent series, whilst in (39) they are defined in terms of the convergent series, through (34). It follows apparently that (34) express the equivalence between the divergent and convergent formulæ.

But it is not a rigorous proof. For there is just this possibility in a proof by comparison. However improbable it may be, it is possible (unless proved to be impossible) for some other combination of the functions I_m and I_{-m} to behave in the same way as regards reducing (32) to identically the form (22). If it did, we should soon find out something anomalous by the impossibilities which would arise on further pursuit. However, I may mention here that in Part 3 of my Paper on "Operators in Physical Mathematics" (May, 1894), I have given an investigation which transforms the I_m and I_{-m} functions to H_m and K_m functions according to (34). It is an entirely different process to the above, effecting the transformation by algebra alone, without any differentiations or integrations. Of this I will give some account in Chapter VII.

The above suggested ambiguity does occur. For if we put $H_m=2I_m$ instead of I_m+I_{-m}, and still use the second of (34), we shall arrive at the same result, equation (39).

Going further, if we use

$$I_m=\rho H_m+\sigma\sin m\pi\, K_m, \tag{40}$$

leaving ρ and σ arbitrary, in place of the first of (34), still using the second, the result is that the right member of (39) is multiplied by 2ρ, so we require $\rho=\frac{1}{2}$ to harmonise the convergent and divergent formula. As for σ, it does not appear in the result at all, so it looks at first as if it were indeterminate, and that

$$H_m=2I_m-2\sigma\sin m\pi\, K_m, \tag{41}$$

with any value of σ. But there is another consideration. The last formula must not contradict the second of (34). Now H_m and K_m are even functions of m, so the last equation makes

$$H_m=2I_{-m}+2\sigma\sin m\pi\,.\,K_m. \tag{42}$$

By addition, we obtain the first relation in (34); and by subtraction the second relation, provided $\sigma=-\frac{1}{2}$, and only then. So the matter is made square.

But I have previously given an investigation which covers the case of integrality of m. I have shown that the operational solution of a certain physical problem, when algebrised in one way leads to the convergent form of the zeroth Bessel function, and in another way leads to the divergent form; thus, $H_0=2I_0$. Now, given a Bessel function of any order, all those differing from it in order by an integer may, as is known, be derived by complete differentiations, as in (18) and (27) above. Therefore $H_m=2I_m$, when m is any integer.

To see what the rigorous mathematicians have to say on this matter, I have referred to the latest treatise (Gray and Mathews). On p. 68, equation (142) is a result given, which, allowing for the difference in notation, harmonises with the second of (34). But the other result given, equation (143), is discordant. It is equivalent to $H_{mx}=2I_{mx}$ in my notation, and is therefore true only when m is an integer, in which case the functions I_m and I_{-m} become identical, as (23) shows. No proof is given in either case.

As regards the algebraical transformation from the divergent to the convergent series, it goes thus. Let

$$B_m(qx,r)=\ldots+\frac{(\frac{1}{2}qx)^{m+2r-2}}{\underline{|m+r-1}\,\underline{|r-1}}+\frac{(\frac{1}{2}qx)^{m+2r}}{\underline{|m+r}\,\underline{|r}} +\frac{(\frac{1}{2}qx)^{m+2r+2}}{\underline{|m+r+1}\,\underline{|r+1}}+\ldots. \tag{43}$$

This B_m function is the generalised Bessel function of the m^{th} order. In it, r is any number positive or negative. If we increase r by 1 it reproduces itself, so it is a periodic function of r. The series is to be continued both ways, unless it stops.

Now in the H, K formulæ, put for ϵ^{qx} and ϵ^{-qx} the following generalised expressions,

$$\epsilon^{qx}=\ldots+\frac{(qx)^{r-1}}{\underline{|r-1}}+\frac{(qx)^r}{\underline{|r}}+\frac{(qx)^{r+1}}{\underline{|r+1}}+\ldots, \tag{44}$$

$$\epsilon^{-qx}\cos r\pi=\ldots-\frac{(qx)^{r-1}}{\underline{|r-1}}+\frac{(qx)^r}{\underline{|r}}-\frac{(qx)^{r+1}}{\underline{|r+1}}+\ldots, \tag{45}$$

where r is as before. In (44) the signs are all +; in (45) they are alternately + and −. On performing the multiplications, the H, K functions are turned into B functions according to the following:—

$$B_m(qx,r)=\tfrac{1}{2}H_m(qx)-\tfrac{1}{2}K_m(qx)\sin\pi(m+2r). \tag{46}$$

Change the sign of m to obtain a second formula. The two formulæ then give H_m and K_m in terms of B_m and B_{-m}.

When r is zero or any integer, B_m reduces to I_m, and we obtain (34) above. In the generalised formulæ (43) to (46), qx should be a real positive quantity, except in special cases.

The identity of I_m and I_{-m} when m is integral, makes the second of (34) assume the 0/0 form. Then take the limit. Thus,

$$K_{mx}=-\frac{1}{\pi}\frac{1}{\cos m\pi}\left(\frac{dI_{mx}}{dm}-\frac{dI_{-mx}}{dm}\right), \tag{47}$$

when m is integral. Or, by (23),

$$-K_{mx}\cos m\pi=\frac{1}{\pi}\left\{2I_{mx}\log\frac{qx}{2}+\frac{(\frac{1}{2}qx)^m f'(m)}{\underline{|0}}+\frac{(\frac{1}{2}qx)^{m+2}f'(m+1)}{\underline{|1}} +\frac{(\frac{1}{2}qx)^{-m}f'(-m)}{\underline{|0}}+\frac{(\frac{1}{2}qx)^{-m+2}f'(-m+1)}{\underline{|1}}+\ldots\right\}, \tag{48}$$

if $f(m)=(\underline{|m})^{-1}$ and $f'(m)$ is its derivative. The convergent formula before given for K_{0x} is a special case of this. The general case presents no difficulty, but requires $f(m)$ to be explained, which belongs to Chapter VII., along with related matters concerning the development of wave formulæ.

Digitized by Google

The reader should be cautioned against concluding that equivalence, as of a divergent and a convergent formula, means identity. The fact that they are different shows that they are not alike in *all* respects, and cannot be interchanged under *all* circumstances. I am inclined to think that this is true even when the equivalence exists between two convergent formulæ of different types, in fact, what rigorous mathematicians call an identity. Or there may be equivalence when the argument is real, but not when it is imaginary or even negative. The extent to which equivalence persists is an interesting matter, but is better observed in the practical concrete examples than theorised about upon incomplete data. Experience and experiment must precede theory.

(To be continued.)

THEORY AND CALCULATIONS OF ASYNCHRONOUS ALTERNATE CURRENT MOTORS.

BY A. HEYLAND (BUDAPEST).

(Continued from page 653).

We will explain the connection between A_1, A_2, A_3, da_1, da_2, with the aid of Fig. 13. We have demonstrated, equations (31), (32B), (33A), that

A_1 varies as $\sin x$
da_1 ,, I_1^2, proportional to $(1-\cos x)$
da_2 ,, I_2^2 ,, $(1-\cos x)$; hence also
(da_1+da_2) ,, $(1-\cos x)$.

The relation existing between $\sin x$ and $(1-\cos x)$ can easily be exemplified with the help of rectangular co-ordinates. With

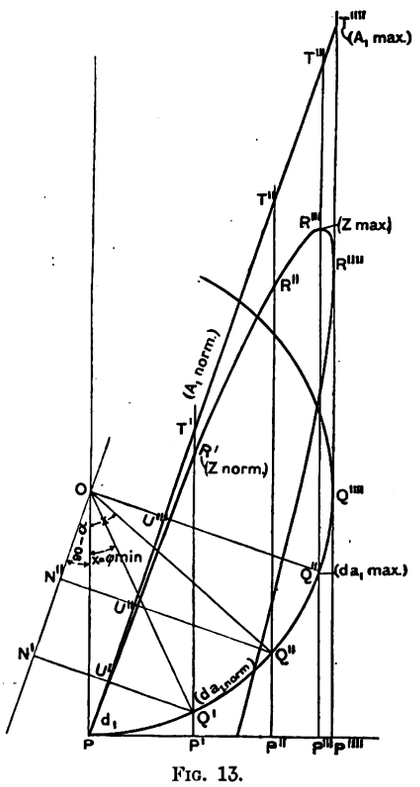


FIG. 13.

radius 1, we describe a circle which passes through the origin, its centre lying on the ordinate, (Fig. 13). If a point moves on this circle, starting from the origin, through the angle x, the abscissa of this point will always be $= \sin x = (PP', PP'' \ldots)$, and the ordinate $= 1-\cos x = (P'Q', P''Q'' \ldots)$. We can now choose the radius of this circle such that the lengths $P'Q', P''Q''$ become equal to the respective da_1 of varying loads. The corresponding A_1 is then proportional to $\sin x$, the abscissa, and can be represented in magnitude by the ordinate of a straight line $P\,T'T''$, which passes through the origin under a certain inclination to the abscissa. We have

$A_1 = P'T', P''T'', \ldots$ proportional to $P'Q', P''Q'' \ldots = \sin x$.

The inclination of this straight line can be found from the conditions of normal load, for which the losses are prescribed. We express these losses at normal power in per cents. of the energy absorbed

$$\frac{da_{1\,\text{norm}}}{A_{1\,\text{norm}}} = \epsilon_1, \qquad \frac{da_{2\,\text{norm}}}{A_{1\,\text{norm}}} = \epsilon_2,$$

$$\therefore \quad \frac{da_{1\,\text{norm}} + da_{2\,\text{norm}}}{A_{1\,\text{norm}}} = \epsilon_1 + \epsilon_2$$

For the normal load x is $\phi_{\min}$. Let this case be marked in Fig. 13 by point Q', so that angle $P\,O\,Q' = \phi_{\min}$. Then $P'Q'$ shall be $da_{1\,\text{norm}}$, and $P'T' = A_{1\,\text{norm}}$, therefore $\frac{P'Q'}{P'T'} = \frac{da_{1\,\text{norm}}}{A_{1\,\text{norm}}} = \epsilon_1$.

We know that $\frac{P'Q'}{PP'} = \frac{1-\cos x}{\sin x}$. If the straight line is inclined at the angle $P'\,P\,T' = a_1$, then $\tan a_1 = \frac{P'T'}{PP'} = \frac{1-\cos x}{\epsilon_1 \sin x} = \frac{1-\cos(\phi_{\min})}{\epsilon_1 \sin(\phi_{\min})} = \frac{\sqrt{1-\cos(\phi_{\min})}}{\epsilon_1\sqrt{1+\cos(\phi_{\min})}}$, and since $\cos(\phi_{\min}) = f$ we find

$$\tan a_1 = \frac{\sqrt{1-f}}{\epsilon_1\sqrt{1+f}}. \quad \ldots\ldots \quad (43)$$

For varying loads, we have

$$A_1 = P'T', P''T'', P'''T''', \ldots.$$

and, in accordance,

$$da_1 = P'Q', P''Q'', P'''Q''', \ldots.$$

$$A_2 = A_1 - da_1 = Q'T', Q''T'', Q'''T''' ; \ldots.$$

or, when we measure off from $T', T'' \ldots, T'R', T''R'' = P'Q', P''Q''$,

$$A_2 = P'R', P''R'', P'''R'''. \ldots$$

A_2 is proportional to the torque Z; the curve $P\,R'\,R''\,R'''$ is, therefore, the torque curve as dependent upon A_1. This curve is, as may easily be shown, an ellipse, and we obtain the important result: *The interdependence between the torque and the work expended is represented by an ellipse.* The torque, we have established, grows with the primary work, but at a slower rate, attains its maximum before A_1 has reached its maximum at R''' in the diagram, and diminishes rapidly.

In order to determine the ratio $\frac{\text{maximum}}{\text{normal}}$ torque $= \frac{Z_{\max}}{Z_{\text{norm}}}$, we draw from $Q'\,Q''\,Q'''$ perpendiculars $Q'U', Q''U'' \ldots$ to $P\,T'$. These projectors measure the variations of the torque, since

$$Q'U' : Q''U'' : Q'''U''' = Q'T' : Q''T'' : Q'''T'''.$$

The maximum is $Q'''U'''$; it corresponds to $Z_{\max}$, and the production of $Q'''T'''$ passes through the centre O. $Q'U'$ denotes normal conditions, corresponding to Z_{norm}.

The ratio $\frac{Z_{\max}}{Z_{\text{norm}}}$ is therefore $= \frac{Q'''U'''}{Q'U'}$.

A parallel to $P'T'$ drawn through O gives us the intersections $N'N'' \ldots$ and we have $\frac{Q'''U'''}{Q'U'} = \frac{Q'''O - OU'''}{Q'N' - N'U'}$.

Further, taking the radius of the circle as unity,

$$\frac{Z_{\max}}{Z_{\text{norm}}} = \frac{Q'''O - OU'''}{Q'N' - N'U'} = \frac{1-\cos a_1}{\cos(a_1 - \phi_{\min}) - \cos a_1}$$

$$= \frac{\sqrt{1+\tan^2 a_1} - 1}{\cos(\phi_{\min}) + \tan a_1 \sin(\phi_{\min}) - 1} \ldots$$

Now, $\tan a_1 = \frac{1}{\epsilon_1}\sqrt{\frac{1-f}{1+f}}$ (43), $\cos(\phi_{\min}) = f$;

hence $$\frac{Z_{\max}}{Z_{\text{norm}}} = \frac{\sqrt{\frac{1-f}{1+f} + \epsilon_1^2} - \epsilon_1}{(1-f)(1-\epsilon_1)}, \quad \ldots \quad (44)$$

or approximately, $$\frac{Z_{\max}}{Z_{\text{norm}}} = \frac{\sqrt{\frac{1-f}{1+f}} - \epsilon_1}{(1-f)(1-\epsilon_1)} \quad \ldots \quad (44A)$$

Digitized by Google

The ratio $\frac{\text{maximum}}{\text{normal}}$ power: $\frac{L_{max}}{L_{norm}} = \frac{A_{3\,max}}{A_{3\,norm}}$ can be developed in the same manner, $A_3 = A_1 - (d a_1 + d a_2)$; we substitute $d a_1 + d a$ for $d a_1$, and consequently $\epsilon_1 + \epsilon_2$ for ϵ_1. The inclination of the straight line P T' be now α,

$$\tan \alpha = \frac{\sqrt{\frac{1-f}{1+f}}}{\epsilon_1 + \epsilon_2}. \quad . \quad . \quad . \quad . \quad . \quad (45)$$

Then

$$\frac{L_{max}}{L_{norm}} = \frac{\sqrt{\frac{1-f}{1+f} - (\epsilon_1 + \epsilon_2)^2} - (\epsilon_1 + \epsilon_2)}{(1-f)\{1-(\epsilon_1+\epsilon_2)\}}. \quad . \quad . \quad (46)$$

The dependence of these two ratios $\frac{Z_{norm}}{Z_{max}}$ and $\frac{L_{max}}{L_{norm}}$ upon f is graphically plotted in Fig. 16*; ϵ_1 has been taken equal $\epsilon_2 = 5$ per cent. The curves show that the capacity for taking any excess of load increases with increasing f at a quicker rate than f, but that the internal losses counteract this increase.

If the internal resistances should vanish, the curves $\frac{Z_{max}}{Z_{norm}}$ and $\frac{L_{max}}{L_{norm}}$ would pass into the curve $\frac{A_{1\,max}}{A_{1\,norm}} = \frac{1}{\sqrt{1-f^2}}$, (37).

The capacity for taking higher loads is augmented by diminishing the internal resistance; the limit is given by

$$\lim_{(\epsilon_1=0)} \frac{Z_{max}}{Z_{norm}} = \lim_{\substack{(\epsilon_1=0)\\(\epsilon_2=0)}} \frac{L_{max}}{L_{norm}} = \frac{1}{\sqrt{1-f^2}}. \quad . \quad (47)$$

The maximum slip which corresponds to the maximum torque is determined by the equations:

$$\frac{S_{max}}{S_{norm}} = \frac{d a_{2\,max}}{A_{2\,max}} \cdot \frac{A_{2\,norm}}{d a_{2\,norm}} = \frac{A_{2\,norm} \cdot d a_{2\,max}}{A_{2\,max} \cdot d a_{2\,norm}}$$

$$= \frac{\cos(a_1 - \phi_{min}) - \cos a_1}{1 - \cos a_1} \cdot \frac{1 - \cos a_1}{1 - \cos(\phi_{min})}$$

$$= \cos a_1 \left(\tan a_1 \cdot \frac{\sin(\phi_{min})}{1 - \cos(\phi_{min})} - 1 \right).$$

Substituting $\tan a_1 = \frac{\sqrt{\frac{1-f}{1+f}}}{\epsilon_1}$, (43), and $\cos(\phi_{min}) = f$, we finally arrive at

$$\frac{S_{max}}{S_{norm}} = \frac{1-\epsilon_1}{\sqrt{\frac{1-f}{1+f} + \epsilon_1^2}}. \quad . \quad . \quad . \quad . \quad (48)$$

If we neglect ϵ_1^2 under the root, $\frac{S_{max}}{S_{norm}} = (1-\epsilon_1)\sqrt{\frac{1+f}{1-f}}$. (48a)

The curve resembles the curve of equation (36) $\frac{I_{1\,norm}}{I_{1\,no\,load}} = \sqrt{\frac{1+f}{1-f}}$; the factor $(1-\epsilon_1)$ is absent in the latter case.

V.—*The torque Z, as dependent upon the slip S and the resistance of the short-circuit coils W_2.*

We have established: $Z = A_2$; $S = \frac{d a_2}{A_2} = \frac{d a_2}{Z}$;

$$\therefore \quad Z S = d a_2,$$

and (Fig. 13) $Z = A_2 = \frac{\sqrt{\frac{1-f}{1+f}}}{\epsilon_1} \cdot \sin x - (1 - \cos x)$.

$$Z S = d a_2 = \frac{I_2^2 W_2}{I_1^2 W_1}(1 - \cos x);$$

again, equation (34), $Z S = f \frac{W_2}{W_1}(1 - \cos x)$.

By eliminating x from these two equations, we find

$$Z = \frac{\frac{2(1-f)}{f(1+f)\epsilon_1^2} \cdot \frac{W_1}{W_2} \cdot S.}{1 + \frac{2}{f}\frac{W_1}{W_2} S + \frac{(1+f)\epsilon_1^2 + 1}{f^2} \cdot \frac{W_1^2}{W_2^2} S^2}. \quad . \quad . \quad (49)$$

* For Fig. 16, see p. 652 of our issue of the 13th inst.—ED. *E.*

As we only wish to inquire into the variations of Z, we may divide the expression by the constant $\frac{2(1-f)}{f(1+f)\epsilon_1^2}$, which yields

$$Z = \frac{\frac{W_1}{W_2} S}{1 + \frac{2}{f}\frac{W_1}{W_2} S + \frac{(1+f)\epsilon_1^2 + 1}{f^2} \cdot \frac{W_1^2}{W_2^2} S^2}. \quad . \quad . \quad (50)$$

ϵ_1^2 being exceedingly small, the fraction $\frac{1-f}{(1+f)\epsilon_1^2}$ is so large that we are justified in omitting $+1$, whereupon

$$Z = \frac{\frac{W_1}{W_2} S}{1 + \frac{2}{f}\frac{W_1}{W_2} S + \frac{1-f}{(1+f)f^2\epsilon_1^2} \cdot \frac{W_1^2}{W_2^2} S^2}.^* \quad . \quad (50A)$$

This equation (50A) gives a curve as plotted in Fig. 14. For $S = 0$ the curve vanishes; for S_{norm} it gives Z_{norm}; for that S which we have designated as S_{max}, Z likewise reaches its maximum; for higher S the curve descends again. To which

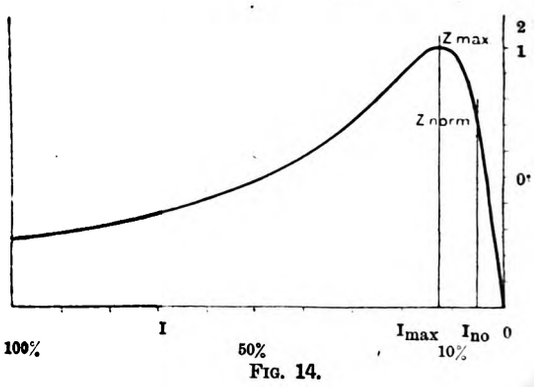

FIG. 14.

value of S the maximum of Z corresponds, can be ascertained by differentiating equation (50), taking S as variable, and setting the differential equal to zero. It will result that

$$Z_{max} \text{ for } S_{max} = f \epsilon_1 \sqrt{\frac{1+f}{1-f}} \frac{W_2}{W_1}, \quad . \quad . \quad (50b)$$

and if we consider that

$$S_{norm} = \frac{d a_{2\,norm}}{A_{2\,norm}} = \frac{d a_{2\,norm}}{A_{1\,norm}} \cdot \frac{A_{1\,norm}}{A_{2\,norm}} = \epsilon_2 \cdot \frac{1}{1-\epsilon_1},$$

we obtain: $\frac{S_{max}}{S_{norm}} = (1-\epsilon_1)\sqrt{\frac{1+f}{1-f}} \cdot f \cdot \frac{W_2}{W_1} \cdot \frac{e_1}{e_2}$.

According to (34)

$$f \frac{W_2}{W_1} = \frac{I_2^2 W_2}{I_1^2 W_1} = \frac{\epsilon_2}{\epsilon_1};$$

therefore: $\frac{S_{max}}{S_{norm}} = (1-\epsilon_1)\sqrt{\frac{1+f}{1-f}}$,

which is the same equation as (48) with ϵ_1^2 neglected as exceedingiy small.

* The relations between torque and slip have recently been very simply deduced by Rothert (*Electrotechnishe Zeitschrift*, Heft. 45, p. 705); in assuming the main field as constant for all loads. By neglecting the decrease of the field with the load in the above equation of the form

$$Z = \frac{aS}{1 + bS + cS^2}$$

the term bS disappears, and we then have

$$Z = \frac{aS}{1 + cS^2}.$$

It is of interest to compare these two equations for the purely theoretical case of no leakage. Then the term with S^2 disappears also, and Rothert's relation

$$Z = \frac{aS}{1 + cS^2} \quad \text{becomes} \quad Z = aS \text{ (straight line)},$$

whilst my relation

$$Z = \frac{aS}{1 + bS + cS^2} \text{ becomes } Z = \frac{aS}{1 + bS}.$$

This is a curve of the same characteristic as Fröhlich's curve of magnetisation.

Digitized by Google

If we consider both S and W_2 as variable, denoting the latter by w_2, we may write

$$Z = \frac{W_1 \frac{S}{w_2}}{1 + \frac{2 W_1}{f}\frac{S}{w_2} + \frac{(1-f) W_1^2 S^2}{(1+f) f^2 \epsilon_1^2 w_2}} \quad . \quad . \quad . \quad (51)$$

in which Z appears as function of $\frac{S}{w_2}$.

The curves of equations (50A), (51) have the same characteristics. So far as Z_{norm} and Z_{max} are concerned, we can refer to Fig. 15. Z becomes a maximum when $\frac{dZ}{d\left(\frac{S}{w_2}\right)} = 0$, in which case

$$\frac{S}{w_2} = \frac{f \epsilon_1 \sqrt{1+f}}{W_1 \sqrt{1-f}} \quad . \quad . \quad . \quad . \quad . \quad (51A)$$

It follows, therefore, that any torque may be developed at any slip, provided w_2 be changed in accordance.

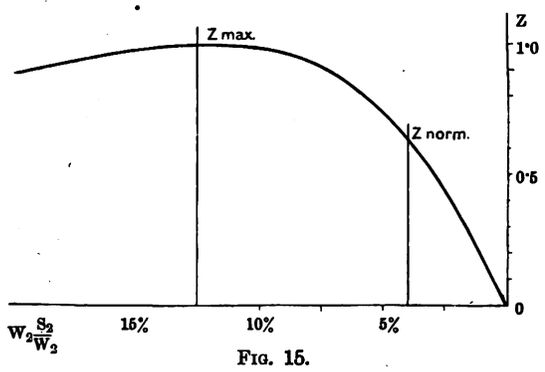

FIG. 15.

If w_2 is changed inversely as S, then the same torque will result for any slip. The normal torque can be obtained for any slip if we add to the armature resistance W_2 an external resistance w_2, such that

$$\frac{w_2 + W_2}{W_2} = \frac{S}{S_{norm}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (52)$$

The maximum torque will then be secured if

$$\frac{w_2 + W_2}{W_2} = \frac{S}{S_{max}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (53)$$

The rule concerning *starting resistance* of the short-circuit armature may hence be stated thus :—

If the motor in starting (slip S = 1) is to develop maximum torque, the starting resistance should be

$$w_2 = W_2 \frac{1 - S_{max}}{S_{max}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (54)$$

If the torque is to be normal,

$$w_2 = W_2 \frac{1 - S_{norm}}{S_{norm}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (55)$$

The starting resistance w_2 should be subdivided at equal intervals.

The motor will, at starting, first develop the normal torque. When we cut out resistance, the torque increases to Z_{max}. When the motor is running the torque will decrease and accommodate itself to the load; the starting resistances can then be cut out successively.

(To be continued.)

THE CLASSIFICATION OF PHYSICAL EXPERIMENTS.

BY E. E. FOURNIER-D'ALBE.

A physical experiment may be defined as the determination of a physical property of a body, or as the investigation of its behaviour under certain well-defined conditions. In accordance with these two definitions two main classes of experiments may be distinguished. Determinations of the dimensions, capacity, weight, density and other normal properties of a body, or the length of a luminous, sonorous or electromagnetic wave, belong to the first class, and would more appropriately be called observations. In every experiment, properly so-called, a body is exposed to a certain test, and its behaviour or reaction is observed and (if possible) measured. Hence we must distinguish three essential elements in every experiment: the body to be experimented upon; the test, action, or circumstance to which it is exposed; and the change or reaction which results. In other words, in our examination of natural phenomena, we must specify the subject, the question and the answer.

Now, a little consideration will show that there are a certain limited number of these elements, viz., bodies, tests, and reactions, and that if these are sorted and arranged in order, it becomes possible to analyse every experiment into its characteristic elements, and to take something like the same step in physics as has already been taken in chemistry, crystallography, and dimensional formulæ by the introduction of symbols. Of these, it will most closely resemble the crystallographic systems of notation, being more qualitative than quantitative, and on that account more comprehensive and less rigorous than chemical formulæ. The object of the present Paper is to specify the characteristic types of experimental elements, and to find a simple and comprehensive classification and notation for the various physical experiments. I believe that this will facilitate the cataloguing of physical researches so far as they have proceeded; the description and survey of the work now being published, by means of symbols capable of international use; and the discovery of gaps in the series of physical investitions which remain yet to be filled up.

1. *Subjects.*—The following are the bodies or things which may form subjects of investigation: Solid, liquid, gas, jet or stream, field ("lines of force"), wave system and ether. Jets or streams may be water jets, flames, liquids or gases flowing through tubes, brush discharges, or such "rays" as are not as yet reduced to wave systems. Fields of force may be gravitational, electric, or magnetic. Wave systems may be gravitational (*e.g.*, water waves), sonorous, or electromagnetic. The last include radiant heat, light and possibly other kinds of radiation recently discovered.

2. *Tests.*—A body may be set in motion or vibration; it may be acted upon by statical force; it may be exposed to a stream, a field, or a wave system; and, finally, energy of various kinds may be imparted to it. The motion may be translational or rotational, or both; the force may be that of compression, tension, shear, or torsion; the vibration may be longitudinal, transverse, or axial: and, finally, the energy may be one of the nine types known—viz., gravitational, elastic, thermal, chemical, luminous, electric, magnetic, acoustic, or kinetic.

3. *Reactions.*—As a result of the experiment, the body may take up any kind of motion, vibration or strain; it may offer resistance, which again may be molar (inertia), molecular (friction), electric or magnetic. It may give rise to a wave system, a stream or a field of force; or it may produce any of the types of energy enumerated. It may transmit, reflect, deviate, absorb or transform a stream, wave system, or supply of energy. It may lead to diffraction, interference, concentration and dissipation or discharge.

Proposed Notation.—It is proposed to use capital and small letters of the Roman alphabet, and some Greek letters, to denote the elements enumerated. These should be chosen so as to agree as much as possible with existing usage, and to give some mnemonic clue to their meaning. Symbols like L length, M mass, T time, F force, H field, R resistance, V potential, and N frequency, are retained, as also *d* difference, *c* constant, *n* number, *p* pressure, *q* quantity, *s* surface, *v* volume, and *t* temperature, while other symbols are immediately suggested by current associations.

The following is a list of the symbols proposed :—

Subjects.

B, body (in general).	J, jet.
S, solid.	H, field.
Q, liquid.	U, undulation (wave system).
G, gas.	X, ether.

Intermediate states of aggregation may be denoted by suitably combining the above symbols, as Q^s for a fused solid, G^Q for a vapour, $(Q+S)^Q$ for a solution, $S = Q$ for a melting solid, $G^Q = Q$ for a condensing vapour, and so forth.

Digitized by Google

The shape of a body may be described by indicating its chief dimensions, using l for a body whose only dimension considered at the time is its length, s for a surface, and v for a solid. Thus, a wire or thread will be denoted by S l, a liquid surface or film by Q s, or an enclosed volume of gas by G v. A closed ring or circuit may be represented by S l^c, a hollow (open) tube by S l^o, and we shall then also have such symbols as Q s^c for a bubble, and S s^o for an open vessel.

Tests.

F, force.
- F p, compression.
- F x, tension.
- F y, shear.
- F z, torsion, twist.

K, motion.
- K x, translation.
- K z, rotation.

O, oscillation, vibration.

H, J, U, as before.

E, energy.
- γ, gravitational.
- σ, elastic.
- θ, thermal.
- χ, chemical.
- λ, luminous.
- ϵ, electric.
- μ, magnetic.
- τ, acoustic.
- κ, kinetic.
- ω, rotational.

As in the case of force, O x, U x, L x will denote a longitudinal vibration, wave and dimension respectively, O y, U y a transverse and O z, U z an axial or central (elliptic or circular) vibration and wave, while L y may denote breadth and L z thickness

Reactions.

R, resistance.
- R M, inertia.
- R m, friction (molecular).
- R ϵ, "resistance."
- R μ, "reluctance."

W, strain (elastic).
- W p, compression.
- W x, extension.
- W y, shear.
- W z, twist.

K, O, U, E, J, H, as before.

Reactions upon U, E, or H:
- e, emission.
- o, transmission.
- r, reflection.
- a, deviation, refraction.
- b, absorption.
- f, transformation.
- u, resonance.
- i, interference.
- j, dissipation, discharge.
- k, concentration, convergence

General Symbols.

- L, length.
- M, mass, molar.
- T, time.
- A, angle.
- Z, sense organ.
- N, frequency.
- n, number.
- q, quantity.
- d, difference.
- c, constancy, constant.
- h, intensity.
- m, molecular.
- p, pressure.
- t, temperature.
- w, vacuum.

I here add, for reference, an alphabetical list of the symbols appropriated, which will also show what letters are still available.

A, angle.	a, deflection.	α
B, body.	b, absorption.	β
C, cohesion.	c, constant.	γ gravitational.
D, rupture.	d, difference.	δ
E, energy.	e, emission, generation.	ϵ electric.
F, force.		ζ
G, gas.	f, transformation.	η
H, field.	g, = "g."	θ thermal.
I,	h, intensity.	ι
J, jet, stream.	i, interference.	κ kinetic.
K, motion.	j, discharge.	λ luminous.
L, length.	k, concentration.	μ magnetic.
M, mass.	l, long.	ν
N, frequency.	m, molecular.	ξ
O, vibration.	n, number.	o
P,	o, transmission.	π = "π."
Q, liquid.	p, pressure.	ς
R, resistance.	q, quantity.	σ elastic.
S, solid.	r, reflection.	τ acoustic.
T, time.	s, surface.	υ
U, wave system.	t, temperature.	ϕ
V, potential.	u, resonance.	χ chemical.
W, strain.	v, volume.	ψ
X, ether.	w, vacuum.	ω rotational.
Y,	x, longitudinal.	
Z, sense organ.	y, transverse.	
	z, axial, central.	

Method of Using the Notation.

The body or subject is put down first, then the test, and lastly the reaction. The three are separated by full stops. Thus, in the determination of Young's modulus of elasticity for a wire, the subject is a wire S l, the test a tensile stress F x, and the result an elastic extension W x. The total experiment is represented by the formula S l . F x . W x. If the ductility of the wire is to be measured, the reaction will be a permanent extension, d L c, and if the tenacity of the wire is to be found, the notation will be S l . F x . D.

To take another example. In saccharimetry the body operated upon is a solution $(Q+S)^q$, the test applied is a beam of polarised light U λy, and the reaction is the rotation or twist of the plane of polarisation about the axis, A z. Hence the formula $(Q+S)^q$. U λy . A z. If we wish to denote that the amount of sugar is the final object of the measurement, we may put in M S (mass of the solid) as a secondary result, separated by a comma, thus: $(Q+S)^q$. U λy . A z, MS.

Similarly, a body may be exposed to several simultaneous actions, which may be indicated in the same manner. Thus the pitch of a stretched string which is made to vibrate transversely would be determined by the experiment S l . F x, O y . N.

When simple measurements (observations) are made the result will be a simple number, n, and the test can, as a rule, be expressed by the symbols already in vogue for dimensional formulæ. Thus we have for the measurement of lengths B . L . n, of densities B . M L^{-3} . n, temperatures B . t . n, and barometric pressures G . p . n.

In some experiments the sense organ plays the most important part. In colour experiments we have U λ . d N . d Z λ, and in music U τ . d N . d Z τ or n U τ . $\frac{N_1}{N_2}$, Z τ—*i.e.*, the effect of a change or ratio of pitches upon the eye or ear.

I may now proceed to give a list of the usual laboratory experiments with their symbolic notation.

Simple Measurements.

Length	B . L . n	Thermometry	B . t . n
Diameter	B . L y . n	Barometry	G . p . n
Thickness	B s . L z . n	Capillarity	Q s . C . n
Area	s . L^2 . n	Wave length	U . L . n
Volume	B . L^3 . n	Angle of prism	So . A . n
Capacity	S s^c . L^3 . n	Photometry	U λ . h . n
Density	B . M L^{-3} . n	Field intensity	H . h . n

Mechanical Properties.

Weight	B . H γ . F	Ductility	S . F x . d L c
Moment of inertia	B . K z . R M	Viscosity	Q . F y . R m
Elasticity	S . F x . W x	Compressibility	Q . p . dv
Tenacity	S . F x . D	Boyle's law	G . dp . dv

Heat.

Expansion—		Latent heat—	
Linear	S . dt . d L	Melting	S = Q . E θ . b
Cubical	B . dt . dv	Boiling	Q = G . E θ . b
Conduction	B . E θ . R θ	Dew point	G^q = Q . t . n
Connection	B . E θ . J,	Vapour pressure	G^q . p . n
Specific heat	B . d E θ . dt	Radiation	B . E θ . e
Freezing point	Q = S t . n	Transmission	B . U θ . o
Melting point	S = Q . t . n	Reflection	B . U θ . r
Boiling point	Q = G . t . n	Absorption	B . U θ . b

Sound.

Velocity	Bo . E τ . L T^{-1}	Refraction	B . U τ . a
Pitch	B . O τ . N	Interference	U τ . U τ . i
Reflection	B s . U τ . r	Resonance	B . U τ . O u

Vibration of Strings.

Law of lengths	S $l\sigma$. d L . O y, d N
„ densities	S $l\sigma$. d M L^{-3} . O y, d N
„ diameters	S $l\sigma$. d L y . O y, d N
„ tensions	S $l\sigma$. d F . O y, d N

Light.

Photometry	E λ . h . n	Polarisation—	
Reflection	U λ . s . r	By reflection	U λz . r . U λy
Refraction	U λ . Bo . a	By transmission	U λs . b . U λy
Dispersion	U λ . d L . da	Saccharimetry	Q + Q^s . U ly . As
Spectroscopy	U λ . Bo, a . L		
Interference	U λ . U λ . i

Magnetism.

Field intensity ... $H\mu . h . n$	Permeability (Ewing)—
Magnetic moment $S\mu . h$, $L . n$	By magneto-meter ..... $Sl\mu . dH . dh$
Hysteresis..... $S\mu . d\mu . Eb$	By ballistic galv. $Sl^c\mu . dH . dh$

Electrostatics.

Electrification—	Diff. Potential ... $2B . dV\epsilon . n$
By friction ..... $2B . Rm . E\epsilon$	Capacity ..... $2B . dV\epsilon . E\epsilon$
By induction ... $B . H\epsilon . E\epsilon$	Sp. ind. capacity $B . dV\epsilon . E\epsilon$
Attraction ..... $2B . E\epsilon . Fx$	Discharge..... $2B . dV\epsilon . j$
Repulsion..... $2B . E\epsilon . Fp$	

Electromagnetics.

Galvanometer ... $Sl^c . j\epsilon\mu . H\mu$	Current induction ... $Sl^c . dH\mu . E\epsilon\mu$
E.M.F..... $(S+Q)^c . E\chi . dV\epsilon$	Thermo-electricity $2B^c . dt . E\epsilon\mu$
Resistance. $Sl^c . J\epsilon\mu . R$	Self-induction ..... $Sl^c . dj\epsilon\mu . R$
Impedance $Sl^c . O\epsilon\mu . R$	
Electro-dynamics. $2Sl^c . j\epsilon\mu . F$	

A few words may now be added on the present state of physical research and its future development, with reference to some peculiarities which have been brought to light by the application of the above system of notation.

Taking the simple symbols as enumerated, the various combinations of them give a large number of types of experiments, some of which have been performed, while others have only, as yet, been very imperfectly dealt with, or not at all. A rough computation of the total number of possible experiments gives 3,200 as a result, eliminating those which are obviously contradictory or futile. Out of these it may be very roughly estimated that between 2,000 and 2,500 have been performed, and their results published, and that about 1,000 experiments remain to be tried. It must, of course, be remembered that all mixtures of subjects and tests are excluded, and also that other subjects and tests may be discovered besides those enumerated.

With regard to the tendency of modern physical experimentation, it may be pointed out that the conceptions expressed by H, U, and X have only in recent times been strictly formulated, and that such things as a rotating magnetic field $H\mu . Kz$ (Ferraris), a rotating electric field $H\epsilon . Kz$ (Arnò), and longitudinal light, $U\lambda x$, have only been heard of within the last few years. The human mind progresses in the direction of dealing with intangible conceptions as material realities, and it may be expected that "fields" and "wave systems" will more and more take the place of "material" bodies at rest or in motion.

Among experiments yet to be performed, I shall only mention a few by way of illustration, leaving their detailed enumeration to a future occasion.

The transformation of energy from one type to another is being gradually carried through all its 72 variations; but the following are as yet only in a very primitive stage :—

$U\epsilon\mu . f . E\chi$	electromagnetic (waves) into chemical energy.
$E\tau . f . \theta$	heating by sound.
$E\tau . f . \lambda$	sound into light.
$E\tau . f . \chi$	"tonography" (analogue of photography).
$E\tau . f . \kappa$	motion by sound.
$E\epsilon . f . \gamma$	"levitation" by electricity.
$E\lambda . f . \kappa$	motion by light (radiometer).
$E\mu . f . \chi$	magneto chemistry.

There are many simultaneous tests which remain to be applied, such as B. F, $U\lambda . W$ effect of illumination upon elasticity. But of all the known types of energy, sound energy is most neglected. Even the measurement of its intensity $E\tau . h . n$ has hardly been attempted yet.

In the immediate future it may, of course, be expected that the greatest share of novelty in discoveries will fall to electromagnetic waves and vacuum phenomena, but problems concerning transformations of energy will always be of paramount importance to science in its practical application.

THE ECONOMICAL CURRENT DENSITY FOR ELECTRIC LIGHT MAINS.

BY JAMES WHITCHER, A.INST.E.E.

In the practical application of Lord Kelvin's well-known law for the most economical current density for electrical distributing mains, several interesting questions arise, involving points of doubt and difficulty that have considerable influence on the result. It is here proposed to discuss these points, particularly as they affect the design of distributing systems for electric lighting. Broadly stated, the law asserts that the most economically efficient conductor for a given purpose, all working and capital charges duly considered, is one in which the annual waste of energy is equal in value to the annual charges upon that part of its capital cost that is directly proportional to its sectional area. It is easily established mathematically, thus :—

Take c = required current in amperes.
a = sectional area of conductor in square inches.
0·045 = resistance of 1 mile of 1 sq. in. copper conductor, laid.
D = the economical current density in amperes per square inch.
v = value of energy per kilowatt-hour in pence.

For the cost of the conductor it is necessary to obtain some relation expressing how it varies with respect to the sectional area. Practically, the cost of copper is directly proportional to a, and the cost of insulation, protection and laying may generally, with fair approximation, be divided into two parts, one in the same simple proportion to a, the other independent of it. Assuming this correct, we have, if p and q be two constants—

P = $pa+q$ = cost in £ per mile of conductor, laid.
s = sum of rates per cent. per annum of interest, maintenance, and depreciation charges on same.

Though the price P may not conform closely to the simple linear relation over a wide range, it may still be considered to do so within limits, the value of the constants being suitably chosen for each limiting interval, on the same principle by which parts of a curve may be taken as practically coincident with tangents at each part. This point will be treated of more fully later on.

Proceeding to equate for the minimum value for the sum in £ of the annual expenses of the conductor per mile, we have, for a constant current flowing for n hours per annum :—

$$A = 0{\cdot}0000001875\, v c^2 \frac{n}{a} + 0{\cdot}01\, s\,(p\,a+q), \quad . \quad . \quad (1)$$

$$\frac{dA}{da} = 0 = 0{\cdot}01\, s\, p - 0{\cdot}0000001875\, c^2 v \frac{n}{a^2}, \quad . \quad . \quad (2)$$

Whence the first term in the equation for A must equal the second, neglecting q, when the conductor is worked at its most economical load : which is the relation the law indicates ; and

$$D = c/a = 400\,\sqrt{s\,p\,/3\,v\,n}. \quad . \quad . \quad . \quad . \quad (3)$$

This is very simple, but looking deeper, one sees that in actual practice the quantities are more interdependent than they are here supposed to be. For instance, increase of conductor loss means increase of generator plant, and v is a very complex quantity depending considerably on the capital charges of the undertaking. It is evident that the meaning of v in these equations is not the usual average or mean cost per kilowatt hour ; it is instead the cost of adding another kilowatt to the rate of output. It is important to remember this, for in many cases the cost of a small addition to the output may be but a small fraction of the mean generating cost under the particular circumstances. For instance, if it cost 200d. to supply at the rate of 100 kilowatts for one hour, the cost of increasing the rate to 101 kilowatts is more likely to be under ½d. extra than to be as much as the average of 2d. Since the economical density when v = ½d. works out to twice the value it has when v = 2d., the difference is of great significance.

To determine how to estimate correctly the true value to be given to v, we must examine the various components that

Digitized by Google

make up the generating cost, and find out which of them enter also into the composition of v, and which are excluded therefrom. The generating cost comprises the following items:—

Interest and other charges on the capital cost of plant.
Labour, supervision and management expenses.
Fuel, water and stores.

The capital cost of an electric light generating station may be very fairly represented in £ by a certain constant sum plus a certain amount per kilowatt capacity of the station. Thus Prof. Robinson has given £(2,500 + 45 X) as a rough approximation to the cost of a station of X kilowatts capacity. This seems sufficient to include a fair allowance for site, buildings and spare plant. Thus, allowing an average of £9 per kilowatt for boilers, pumps and piping, £15 for steam dynamos or alternators, £3 for switchboard, &c., £1 for site, £7. 10s. for buildings, and £2 for stack, settings and flues, the total per kilowatt is £37. 10s., which, with 20 per cent. spares, amounts to £45. Generally, therefore, £45 will represent the complete cost of adding each extra kilowatt to the capacity of the generating plant. The amount of the constant sum, £2,500, or whatever it may be, has clearly no influence upon v, and it may be ignored.

On considering the second item of working cost, it is seen that a large proportion of it is essentially independent both of the output and the dimensions of the station. Three shifts of attendants must be provided, and a great part of the managing expenses must be considered as constant over wide ranges. Further, the increments are of necessity large, and made at wide intervals. Neither plant nor labour can be bought or engaged in small increments or at uniform rates, and the mode of increase or decrease must be essentially discontinuous, with very pronounced steps. Thus the rate of output during a given shift may be augmented by, say, 250 kilowatts before an extra stoker is required; by 500 kilowatts for an extra driver; and by, say, 1,000 kilowatts for an extra switchboard hand. On this liberal basis the annual cost of extra labour for additional output rate of 1,000 kilowatts for one shift per diem will approach £750; allowing £250 for extra managing charges, this becomes equivalent to £1 per kilowatt. If the duration of this same increase extended into two shifts per day, it would be £2. Now there is an element of luck here in the fact that the debt thus incurred to the labour account may not fall due for years ahead; therefore it is worth giving a hostage to fortune, and omitting, say, one-half of this charge from inclusion in v.

The rate for fuel and stores must be taken on the assumption that the stand-by and constant losses have settled down to something like their final proportion of the whole. These only appear in v in virtue of their proportionality to the capacity of the plant, which relation, for simplicity's sake, we will consider a simple one. Apart from them the cost for this item would scarcely ever exceed 0·25d.

Assembling the several items, we may write v thus:—

$$v = 108\, s_1/n + 120/n + k/n + 1/4 \quad \text{pence.}$$

Here s_1 is the percentage rate of capital charges on the generating plant. Taking the interest charge at 3·5 per cent., the sinking fund at 1·1 per cent. (to sink the capital in 42 years), and the maintenance rates to cumulate to 5·4 per cent. of the total £45, s_1 will sum up to 10 per cent. The second term (for labour) is correct only when n is less than 3,000 hours. In the third, k represents the annual cost, per kilowatt capacity of plant, of the stand-bye and constant losses; presuming that when n is 1,000 hours the approximate value of this term will be 0·25d., k will equal 250. Hence,

$$v = 1450/n + 0{\cdot}25.$$

When $n = 1{,}000$, $v = 1{\cdot}7$; when $n = 2{,}000$, $v = 1$ nearly, which illustrates how greatly it varies with n.

To fit practical conditions more accurately, the depreciation charges should not be treated as wholly constant and invariable in respect to n; for it is obvious that they would be much influenced by the number of working hours. A more appropriate convention in estimating maintenance, is to make a constant or "standing" charge, at, say, 1·4 per cent., and a "running" charge of 0·2d. per kilowatt hour per annum, which is equivalent to depreciation at the rate of 2 per cent. per 1,000 working hours. From this point of view, $v = 900/n + 0{\cdot}45$d. Thus, for most practical cases, the value of v will be somewhere between 1d. and 2d., and. 1½d. is a useful general average to take. Opportunity has been taken to discuss it thus fully because the quantity is one that enters into many practical problems besides this.

We may now proceed to examine the quantity p. It is the amount, in £ per mile, of that proportion of the cost of a 1 sq. in. conductor laid complete, which appears simply proportional to the sectional area, assuming the remainder constant. Evidently this also is a very involved quantity. In determining its limits, it may be observed that, firstly, the cost of trenching and making good is practically independent of the size of conductor. Secondly, the cost of protection, meaning the conduit, pipe, or casing enclosing the conductor, is also largely independent of its size. Thirdly, the cost of insulation depends in a great measure upon the section; and fourthly, the cost of copper is entirely dependent thereon.

With copper wire at 7d. per pound, the fourth item is £600. Inspection of makers' price-lists shows that for insulated conductors the extra cost per mile of an additional 0·01 sq. in. of section varies for various classes, makes and sizes of cables somewhat as follows:—

Single, vulcanised rubber,	braided,	5,000 megs.	£18	to £27.
,, ,,	,,	2,000 ,,	£16	to £24.
,, ,,	,,	600 ,,	£14	to £20.
Concentric ,,	,,	high insulation,	£50	to £60.
Single, lead-covered,	fibrous or paper,	low insulation,	£12	to £16.
,, ,,	,,	high ,,	£14	to £20.
Concentric ,,	,,	low ,,	£24	to £28.
,, ,,	,,	high ,,	£30	to £36.

The higher price refers to small size conductors, the lower to large sizes. The limits contain prices of most well-known makes and common sizes; but it is inevitable that there should be many exceptions and eccentricities in such figures. A general mean is about £18, or £1,800 per square inch; and since the copper alone is £600, the insulation accounts for £1,200. That is, that figure is roughly representative of the value of the variable part of the third section of the conductor cost. With the constant parts there is no need to trouble, the complete cost P not being required.

How far the cost of protection varies with the size of conductor depends upon the method employed. Taking the method of armoured mains laid in the ground direct first, we find that the amount to be added to the above figures to represent the cost of armouring varies very irregularly. The commoner values are between 10s. for large cables and £3 for small, but makers' methods of pricing the armouring are too diverse to agree with any general limits or averages. With most conduit, casing and pipe systems the cost varies very little with the size of mains. By working out examples results are found similar to the figures given for armouring —that is, the additional expense incurred on the item for protection when the sectional area is increased is at some rate between £50 to £300 per mile per added square inch of section. We may conclude that the constant p will be about £1,500 for large low-pressure mains, and £2,000 for average high-pressure mains. For heavy bare copper mains in brick culverts, according to Mr. Crompton's figures published some years ago, it would be about £700.

As regards s, the sum of the rates of capital charges on the cost of conductor, the interest and sinking fund rates will be the same as those due on the generating plant, for instance, 3·5 per cent. and 1·1 per cent. For maintenance, one must be careful not to take a fancy rate, for practically this appears to prove very small. Probably 2 to 3 per cent. will not err far from the truth either way; but, of course, as jointing is the weak point, very much depends on the number of joints on a main and the care with which they are made. This makes the average for s about 7 per cent.

In the above the supply is considered to be a constant current, maintained for a definite number of hours per annum. This meets the case of series arc lighting; for the usual parallel systems, the equations must be modified by certain multipliers.

Digitized by Google

To determine the losses in a conductor carrying a varying current, the mean square of the current needs to be found. This is the quantity which corresponds to c^2 in the preceding; multiplied by the resistance and hours of supply per annum, it gives the annual conductor loss in watt-hours. To work out this mean from 365 daily load curves is too big a task to contemplate. However, it has been found that its most general values for electric lighting stations fall between the limits 0·04 and 0·16 of the maximum current reached. That is for a continual supply, or 8,760 hours per annum. Call the ratio t. In estimating v in this case, n means the number of hours of maximum load which would result in equivalent conductor loss. That is, $n = 8{,}760\,t$. Likewise, if we take D as the maximum current density, c as the maximum current, and n as above, the deductions already given for constant current supply apply to varying supply also.

When the current differs in various parts of the main, as in distributing mains tapped at many points, the loss depends upon the mean square of the current values at each successive section. Thus, for an evenly distributed load, where the current decreases regularly in arithmetical progression, from a maximum at the feeding point to zero at the far end, the mean square is one-third the maximum square. Therefore, if we here consider D and c to be the initial density and current, the new value of D to fit this instance will be $\sqrt{3}$ times the density appropriate if the initial current be carried the full length of conductor.

Finally, since v closely follows a law expressed by

$$v = S/n + V, \text{ or, } v = S/N\,t + V,$$

for constant currents

$$D = 400\sqrt{sp/3(S + V\,n)};$$

for varying currents,

$$\text{Max. } D = 400\sqrt{s\,p/3(S + V\,N\,t)};$$

each subject to a multiplier to give initial density if the load is distributed.

With the values for capital charges, &c., suggested above, we have practically, for high-pressure constant current mains—

$$D = 40{,}000/\sqrt{2{,}000 + n},$$

or when

$n =$	500	1,000	1,500	2,000	2,500	3,000	3,500	4,000,
D =	800	750	675	630	600	580	525	500.

For high-pressure feeders when $n = 8{,}760$—

$$\text{Max. } D = 900/\sqrt{1 + 4{\cdot}4\,t},$$

or when						
	$t =$	0·01	0·1	0·16	0·22	0·3,
	D =	830	750	690	650	600.

For low-pressure feeders, max. $D = 800/\sqrt{1 + 4{\cdot}4\,t}$, and grades from 750 to 550 for above values of t.

For low-pressure distributors, evenly loaded (maintenance rate raised to 4·4 per cent.), max. initial $D = 1{,}500/\sqrt{1 + 4{\cdot}4\,t}$, grading from 1,400 to 1,000.

For bare copper feeders, max. D = 500 to 400. For bare copper distributors, max. initial D = 900 to 700.

The noteworthy point about these figures is the comparative constancy they show over a wide range of load-factors. Accurate estimate of the latter is of no consequence therefore. They show that the economical density is limited to a much narrower range than that given by calculations based on the arbitrary and erroneous assumption that r is a constant quantity. The feeder and distributor densities given by above methods are the average for all on the system. It may be that one feeder has a load curve, the maximum of which occurs at a different time to that of the others. The density in this feeder should be increased, and that in the others decreased, the average remaining the same. For if we have a main supplying current (from same plant) *only when* the major load is off the station, in determining the density for this main, v ought to be taken at something less $\frac{1}{2}d.$; since none of the fixed capital charges, and probably none of the labour charges, can be properly debited against it. It would be pure waste to design such a main for the same density as those for the normal load

ON TELEPHONIC DISTURBANCES CAUSED BY HIGH-VOLTAGE CURRENTS.*

BY DR. V. WIETLISBACH

(Chief Engineer of the Swiss Telegraph Department).

After a brief summary of the conflict of interests between telephone and power undertakings the author proceeds as follows:—

The injurious disturbances to telephone lines, in so far as they are traceable to the action of the electric current, may be considered under three heads:—

I. The high-voltage current may enter the low-voltage line in consequence of accidental contact with a telephone wire, or in consequence of other accidents, such as the fracture of a pole, support or wire. If the tension of the intrusive current be high, the intensity of the current may become so great as to destroy the telephone apparatus or melt the telephone conductor; or again, the latter may become so overheated as to ignite any wooden parts near it, and thereby set even large telephone stations on fire, such occurrences having already occasioned damage amounting to millions of francs.

II. When the high- or the low-voltage line is either uninsulated, or insufficiently insulated from earth, or when both lines are carried on the same poles or supports, part of the high-tension current may enter the telephone line through earth not only occasionally, *i.e.*, under exceptional circumstances, but permanently. If the high-voltage current be a perfectly constant direct current, such as, *e.g.*, that supplied from a storage battery, no effect is noticeable in the telephone except that the sensitiveness of the apparatus is somewhat impaired when the tension of the high-voltage current exceeds a certain limit. But if the high-voltage current be pulsating, which it always is where continuous current is used for driving car motors; or, again, if the high-voltage current be a single or polyphase alternating current, a humming noise is set up in the telephone apparatus, the humming being less violent in the case of a pulsating direct current, but very violent in the case of an alternating current, so that in either case telephonic communication may be rendered difficult or altogether impossible.

III. The high-voltage current affects low-voltage lines in the neighbourhood by induction, *i.e.*, to every rise and fall of the high-voltage current there is a corresponding electric wave in the telephone line, the intensity of that wave being proportional to the oscillation in the high-voltage line; in other terms, a succession of waves in one conductor is reproduced by a similar succession of waves in the other. There is an essential difference in the effect of electromagnetic and electrostatic induction. In both cases the electromotive force is proportional to the magnitude of the change in the primary, *i.e.*, the inducing current, and is governed by the reciprocal position of the lines and by the distance over which the two lines run parallel to each other.† In the case of electromagnetic induction, the intensity of the induced current set up is inversely proportional to the resistance, *i.e.*, it decreases as the length increases. On the other hand, in the case of electrostatic induction, the intensity of that current is proportional to the capacity of the affected line, and, therefore, also proportional to the length of the latter. Hence electromagnetic induction predominates, generally speaking, in short lines, and electrostatic induction in long lines, independently of the distance over which the two sets of conductors run parallel to each other.

The disturbances considered under I. may be counteracted by lead fuses inserted in the telephone line at the point where the latter enters the building, and which melt when the intrusive high-voltage current exceeds one ampere. By that means the line is interrupted, and damage to the telephone apparatus is rendered impossible. There is no difficulty in constructing safety fuses which are far more sensitive than those mentioned; but they offer no practical advantage, because they melt much too easily even in the case of very light thunderstorms, and hence only produce innumerable interruptions which greatly interfere with the regular working of the telephone service.

When the tension in the high-voltage line exceeds 500 volts, the arc which forms at the safety fuse is not immediately extinguished, and may, therefore, become even more dangerous than the high-tension current itself. In such cases special devices are necessary in order to prevent the formation of an arc or to ensure its immediate extinction when formed. To this end, the wire fuse is enclosed in long glass tubes or imbedded in sand, and no combustible materials must be kept in the immediate neighbourhood. With a view to prevent the bursting of the glass tubes or render the

* Translated by Dr. C. S. du Riche Preller. This Paper is a Report just published at Berne (*Blätter für Electrotechnik*), and was kindly communicated by Dr. Wietlisbach to the translator. The translator is of opinion that it strikingly confirms the facts and conclusions recently set forth by him in *The Electrician* (January 10, 1896, "Electric Tramways and Telephonic Disturbances"). The author uses the term "high-voltage currents" (500 volts and above) as contrasted with low-voltage telephone currents.

† [The phraseology of what follows is not so clear as could be wished, but it is a faithful rendering of the original.—ED. *E.*]

Digitized by Google

bursting harmless, they are encased in fibrous material. When an intrusive current of sufficient amount arrives at the wire-fuse, the latter is explosively vapourized and the vapour is expelled from the glass tube. The explosion at the same time extinguishes the arc if such be formed. There are various other means of counteracting the overheating of telephone wires and apparatus; but the higher the tension the more complicated and inconvenient are the safety contrivances.

The disturbances considered under II.—*i.e.*, the humming produced in telephone apparatus by intrusive undulating or alternating currents, may be avoided by insulating the telephone line as carefully as possible from earth, as well as from any parts which may be connected with the high-voltage line. But when the tension in the latter exceeds 500 volts, that precaution is not always sufficient, the less so because, in practice, it is impossible to maintain either high- or low-voltage lines at all points and permanently in a state of perfect insulation. The practical application of both classes of currents frequently involves the necessity of installing the conductors in damp, or otherwise unfavourably situated places, business premises, &c.; and having regard to the high tension of the one class of installation and the extreme sensitiveness of the apparatus of the other, an almost infinitesimal leakage, amounting to only one millionth of the total current, suffices to produce a very marked telephonic disturbance. It is on this account that the juxtaposition of the two can be rendered bearable only by carefully insulating *both* systems from earth. It is, moreover, but fair to require that the conditions which are imposed upon one class of installation should also be made obligatory upon the other, if it be for the general and public advantage.

The telephonic disturbances most difficult to deal with are those considered under III.—*i.e.*, those due to induction. The most effectual means of combating this class of disturbance consists in doubling the telephone conductor, the two wires being placed as closely as possible to each other, and the telephone apparatus at each terminal being inserted between them.

A high-voltage line in proximity to the double telephone line will produce in each of the two wires a disturbing current which will flow to the same terminal, where both currents compensate each other; no disturbance will, therefore, be noticeable in the telephone apparatus. When the disturbing cause is not of excessive magnitude, this remedy will give satisfactory results. But when, on the other hand, the value of the disturbing current is several hundred or several thousand times greater than that of the normal telephone current, the remedy must of necessity fail. In that case corresponding precautions are required also in respect of the high-voltage line—*i.e.*, the latter must, like the telephone line, be provided with a metallic return, the two wires being placed in close proximity to each other, and requiring, moreover, a very high degree of insulation. Currents of approximately equal amount will then flow in both the high-voltage wires in opposite directions, and the same will apply to currents which are thereby induced in the telephone line, and which will, therefore, virtually neutralise each other.

Thus, in respect of the difference of induction, a twofold effect is obtained: one between the high-voltage, and another between the low-voltage wires; and it only remains to place the two lines at such a distance apart from each other as will ensure the noise being sufficiently deadened. This distance is obviously governed by the parallel length of the two lines and by the nature of the inducing high-tension current. In order to get rid of the noise altogether the two pairs of wires should, moreover, be placed in a properly-defined reciprocal position. Suppose the wires 1 and 2 to form the high-voltage circuit, and the wires 3 and 4 the low-voltage circuit, and suppose r_{13}, r_{23}, r_{14}, r_{24} to be the distances between them, the equation for reducing the inductive effect to 0 is—

$$r_{13} \times r_{24} = r_{23} \times r_{14}.$$

In practice, however, this result can only be obtained approximately. The complete metallic circuit gives satisfactory results only when the insulation is perfect at all points, and the two component parts are electrically and in every respect perfectly symmetrical. This desideratum is attainable in short telephonic lines, but to permanently maintain this perfect condition in telephone lines extending over hundreds and thousands of kilometres, is a practical and technical impossibility.

This is obvious from the following considerations: When at the terminal of a telephone line of say 500 kilometres (312 miles) in total length, a high-voltage current line runs parallel to the telephone line for a few hundred metres, a single point of defective insulation, *e.g.*, the contact with the branch of a tree at the other terminal, suffices to immediately produce along the whole telephone line a noise so marked as to render telephonic communication absolutely impossible. Nor is this all. When the noise is sufficiently violent it spreads to all the other telephone lines which use the same poles as the disturbed line for part of the total length of the latter.

When, for example, a slight defect occurs in the telephone line from Zurich to Geneva, the noise produced by a high-voltage installation, *e.g.*, the electric tramway in Zurich, spreads not only from Zurich to Geneva, but makes itself more or less felt in all lines which, for part of the distance, use the same poles. Hence the noise is perceptible also at Lausanne, Berne, Fribourg, Neuchatel, Bienne, Chaux-de-Fonds, Basle, and generally throughout the telephonic system of Western Switzerland. Under unfavourable circumstances, *i.e.*, when the noise is particularly violent, it may even, by secondary or tertiary translation, spread from the Zurich and Geneva line to the Berne and Basle line, thence to the Basle and Bienne line, and thence to the Bienne and Chaux-de-Fonds line at the points where Basle-Bienne runs parallel, not to Zurich-Geneva, but only to Berne-Basle, and again, where Bienne-Chaux-de-Fonds runs parallel only to Bienne-Basle.

This phenomenon is one of the most difficult to deal with, and is, as a rule, not sufficiently taken into account. The telephone system of Switzerland now comprises a total wire length of about 60,000 kilometres (37,500 miles),* and it is therefore obvious that the task of maintaining so large an aggregation of lines at all points in faultless condition is by no means an easy one. In many cases the only way to obtain a fairly satisfactory result is to bury the specially exposed or affected sections of a telephone line underground; but it is not worth while to incur the trouble and expense which that operation involves, unless a large number of telephone wires can be buried at the same point and at the same time.

A further remedy consists in translators, which correspond to the transformers of high-tension installations, and which connect two sections of a telephone line electrically by electromagnetic induction, but at the same time prevent the injurious effect of a fault in the line, *e.g.*, leakage to earth, abnormal resistance, &c., being transferred from one section to the other. The effective capacity is, by this means, also lessened. When, *e.g.*, the telephone sections Zurich-Berne and Berne-Geneva are connected by a translator at Berne, any leakage which may take place in Geneva does not affect the Berne-Zurich section. The efficiency of translators does not, however, exceed 90 per cent., and though they furnish a means of restricting the effect of a telephonic disturbance to a given section of the entire line, they involve, on the other hand, a loss of energy.

Other remedies, such as a differential arrangement of wires, Muller's method of running the wires, &c., can only be regarded as of minor importance; for though they may render valuable service in special cases, they are not suitable for general application.

The noise produced in the telephone by a disturbance varies, of course, greatly in degree, and depends essentially on the amount of the high-voltage current and on the parallel length of the high and low-voltage lines. Where the high-voltage line is well insulated from earth, and the wires constituting the high-voltage circuit run parallel to each other, it is, in the majority of cases, and in conjunction with the metallic return, also of the telephone line, practicable to place the two lines in juxtaposition for short distances not exceeding a few hundred metres, even in the same street. But when the parallel length extends over one kilometre or more, the noise may be distinctly observed, even though the two lines be as much as 100 metres or more apart. It would seem that the configuration of the ground, too, may exert a certain influence. When the high-voltage line, *e.g.*, that of an alternating current installation, is insufficiently insulated, or, what is worse, is connected to earth, a single crossing of the telephone line, even though it be at right angles, suffices to produce in the telephone a humming disturbance of a very marked character.

Conspicuous among high-voltage installations connected to earth are the majority of electric tramways. As a rule, these tramways are worked with continuous current, which is, however, by the motion of the motor cars converted into a pulsating one. And since the current is conveyed only by one wire, and the compensating effect of the metallic return is wanting, the telephonic disturbance is much greater in proportion. In Switzerland there is only one electric tramway which, instead of using earth, *i.e.*, the rails as return, has a complete metallic circuit constituted by two overhead wires, to wit, the Vevey Montreux-Chillon tramway. The effect of the working of this tramway upon the telephone line running along the same road is noticeable where that telephone line is only single with earth return, but the slight noise disappears almost entirely where the same telephone line has two wires.

All the other electric tramways so far constructed in Switzerland use only one conductor, which is suspended above the rails, and from which the continuous current is conveyed either by trolley wheel or by slide contact to the motors of the cars, whence it passes through the car frame and wheels to the rails, and through the latter is intended to flow back to the generator. The rails are generally imbedded in the roadway, and more especially in wet weather insulation is either defective or is wanting altogether, the insulating resistance being only 15 to 20 ohms per kilometre. Hence, a more or less large proportion of the current spreads

* This is equal to 20 kilometres (12.5 miles) per 1,000 inhabitants.—TRANSLATOR.

Digitized by Google

through earth or straggles back to the generator by water and gas pipes, or by telephone wires, the telephone lines connected to earth being thereby subjected to the intrusion of the high-voltage tramway current. In order to obviate this, the rails should be insulated from earth as well as possible, and that might be accomplished by imbedding them in cement or asphaltum. Experience tends apparently to show that where the permanent way is imbedded in wood pavement, the loss of current is greatly mitigated.

A further means of counteracting the spreading of the high-voltage current through earth consists in insulated cables laid underground from the generator to the points of greatest load of the tramway system, and at these points connected with the rails. By this means, high differences of potential between the different sections of the tramway system are avoided. Of course, the rail joints must be such as to ensure adequate conductivity; this can be enhanced by bare copper wire. With the aid of these various expedients, it is possible to keep down the leakage of current from the rails within certain limits, while, in specially difficult or serious cases, there always remains the remedy of replacing the earth return of the telephone lines by a complete metallic circuit.

Far more difficult is it to deal with the effects of induction which latter, as already stated, is due to the continuous current, supplied from the generator becoming an undulating one owing to the motion of the cars. Two causes suggest themselves as operating to bring about this effect. One is the motor itself, during rotation of which successive pairs of commutator segments, connected to corresponding armature coils, are alternately short-circuited under the brushes. The effect produced thereby may be somewhat mitigated by increasing the number of commutator-segments which will also result in raising the noise to a higher pitch. The other cause will be found on the line itself, *i.e.*, at the point of contact of the conductor with the collector, in this case the trolley wheel. This latter is fixed to an elastic rod which, upon the car being started, assumes a vibratory motion. Moreover, the contact wire, which in this respect behaves like a drawn cord, also experiences considerable vibrations as the trolley wheel runs along its surface. Consequently, and as in the similar case of a microphone, the resistance at the point of contact undergoes a change, and the result is an undulating current. In fact, the inductive noises separately produced by the two causes referred to, *i.e.*, the motor and the trolley wheel, can be distinguished side by side in the telephone apparatus.

It is curious to note that the noises produced by different electric tramways of similar construction vary considerably in degree, and, further, that these noises are, as a rule, comparatively slight when the tramway has just been opened for traffic, and that only in the space of a few weeks do they attain an intensity which renders telephonic communication difficult. It is not clear how this gradual change takes place, if at all, in the motors; on the other hand, it may conceivably be due to the contact wire, which gradually becomes loosened at the insulators, while the supports, too, attain greater play and move more freely in consequence of the constant vibrations to which they are subjected.

That the mode of contact is also a factor in the phenomenon referred to appears probable from the further fact that the increasing intensity of the noise is observed chiefly on tramways where the current is collected from the contact wire by trolley wheels, whereas tramways using slide contact-bars or shoes experience that phenomenon in a far less degree. An important difference between the two systems consists in the circumstance that where the trolley wheel is used, the contact wire must be suspended as exactly as possible over the axis of the tramway, in order to prevent the trolley wheel jumping off the wire, whereas in the case of the slide-bar or shoe, so high a degree of accuracy is unnecessary, and the contact wire therefore requires fewer points of suspension, nor need it be drawn so tight. In the former case the elastic vibrations of the contact wire are of high frequency, and correspond to the acoustic waves perceived by the ear. In the latter case, on the other hand, the vibrations are of so low a frequency—*i.e.*, so slow—that they fall outside the range of perceptibility of the ear. The aerial crossings and bifurcations of trolley tramways involve much greater difficulty of construction than those of tramways with slide contact, and when the electrical connection or the insulation at those points is defective, such defects will likewise aid in aggravating the phenomenon referred to.

In some quarters great weight is further attached to the lubrication of the contact surface. Be that as it may, the fact is attested and confirmed that some electric tramways produce in telephone lines only slight or moderate disturbances which can easily be obviated or neutralised, whilst other electric tramways cause telephonic disturbances of so marked or violent a character that even mere crossings of telephone lines having metallic return and possessing a somewhat high capacity suffice to render telephonic communication extremely difficult.

In such cases, the only remedy is to bury the telephone lines which are in proximity to the tramway underground. Having regard to the considerable expenditure which the laying of such cables involves, it would certainly be worth while to further investigate the causes of those telephonic disturbances which may presumably be obviated by very simple means. As regards cost of construction, electric tramways which do not cause telephonic disturbances are in no way more complicated or more costly than tramways which do produce the noises referred to. It is even reasonable to presume that the wear and the cost of maintenance are less in the former than in the latter case.

Electric tramways having underground conductors will, presumably, not give rise to telephonic disturbances. On the other hand, it will not be out of place to mention one electric tramway which is now in course of construction, and which it is proposed to work with three-phase current, two of the conductors being constituted by two overhead wires, and the third conductor by the rails. In this case, it is no longer a question of an undulating current whose oscillations might possibly be mitigated by electro-mechanical means, but of a high-tension alternating current, which to the telephone lines simply means unconditional surrender. It is obvious that here the low-voltage *i.e.*, the telephone, lines will have to give up their earth return over a wide range. But the high-tension system referred to claims to be paramount even in the aërial space. Double telephone wires of low capacity are practicable only for parallel lengths of a few hundred metres; for as soon as the capacity increases, the amount of the intrusive high-tension current exceeds that of the telephone working current. Under these circumstances, the only means of rendering the regular working of the telephone service possible is to bury all the aërial telephone wires underground; only this is no longer a case of equable compromise, but of being overcome by brute force.

In dealing with telephonic disturbances, it must be borne in mind that the radius of telephonic communication from a given centre increases, in accordance with the demand of the public, from year to year. Originally it extended to a few hundred metres, then to several kilometres, whilst the radius is at present several hundred, and will soon be several thousand kilometres. With this rapid growth the strain on telephone apparatus and installations increases also as a whole, and it is no easy task to maintain them always in the required degree of efficiency. If, therefore, the working of the telephone is not to be in a great measure restricted and its efficiency impaired by the disturbances caused by high-voltage currents, these disturbances cannot be permitted to make themselves felt in telephones more than other accidental sounds or noises governed by meteorological and other conditions.

A high-voltage installation may produce a noise which *per se* has no disturbing effect on telephones, but the same telephone line may, in a length of several hundred kilometres, come in collision with 20 or more high-voltage installations, and the sum of all the disturbances produced by those installations collectively will suffice to give a death-blow to the telephone.

There is, therefore, a wide and fundamental difference between a short telephone line which only serves to connect two local points (*e.g.*, an electric generating and a motor or other service station), and a telephone installation for interurban and long-distance service. The difference between the two cases may be likened to that between a horse tramcar jogging along through a town at the rate of 8 kilometres per hour, and an international express train covering a distance of thousands of kilometres at the rate of 100 kilometres per hour.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, March 27th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read: (1) "The Electromagnetic Effect of Moving Charges," by G. W. Morton; (2) "Quantitative Measurements of the Edison Effect in Glow Lamps," by Dr. J. A. Fleming, F.R.S.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at St. James's Hall Restaurant.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "New Researches on Liquid Air," by Prof. Dewar, F.R.S.

SATURDAY, March 28th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture (VI.): "Light," by the Right Hon. Lord Rayleigh, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

3:30 p.m Students' Visit to the Metropolitan Electric Supply Company's Station. Meet at Amberley-road Station.

INSTITUTION OF JUNIOR ENGINEERS.

7:30 p.m. Conversazione at the Westminster Palace Hotel.

TUESDAY, March 31st.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read and discussed: "The Tampico Harbour Works," by Dr. E. L. Corthell.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

GOOD-FRIDAY WEEK.

"THE ELECTRICIAN" will be published on THURSDAY in Good-Friday week instead of on Friday. Communications intended for this issue must reach us not later than Wednesday morning's post.

Alterations to existing Advertisements and copy for new Advertisements should reach the Publisher on Tuesday, but in any case not later than Wednesday morning.

COMPETITION IN ELECTRIC SUPPLY.

There is nothing to equal a long bout of commercial prosperity for engendering healthy notions with regard to competition. When our competitors are being beaten out of the field it is the easiest possible thing to subscribe to the doctrine that "to be protected against competition is to be protected in idleness, in mental dulness," and to believe in the double blessedness of price-cutting. But no sooner does the tide turn than the vague but expressive phrases such as "unfair competition," "demoralising competition," become fashionable. Only yesterday it was distinctly heterodox to so much as question the unbounded beneficence of unlimited competition; to-day the pass-word is either "regulated," "potential" or "limited" competition.

Possibly it was the trend of public opinion in this direction that induced the Metropolitan Electric Supply Company just recently to fee the lawyers and fight the Charing Cross and Strand Electricity Supply Corporation. More probably the Company was actuated by the idea that to quietly condone an invasion of its huge territory would be to encourage raiders generally, and its advisers, no doubt, thought that there was a greater probability of winning a victory in Committee than of rendering the Company's position absolutely impregnable from the electro-technical point of view. It is notoriously difficult to prove a negative, and still more difficult to prove to demonstration that all a competing company is likely to do has already been done by the company in actual possession. Mr. BALFOUR BROWNE certainly did his best for his clients. His picture of the evils of competition would have been positively alarming—had it been drawn by anyone else. If all Mr. BROWNE says be true there is evidently a bad time in store for some one. "Where competition was allowed between two companies in one district it invariably resulted in the bankruptcy of one of the companies. Com-

Digitized by Google

petition between such companies inevitably led to combination, and combination was nothing but a conspiracy against the public. If this Bill passed the result would probably be that either the Metropolitan or the Charing Cross Company would become bankrupt, and the surviving company would have to buy it up, and then charge higher prices to recoup itself." Prave ords! But as they are only the eloquent vaticinations of counsel, we will not stop to inquire too minutely how the bankruptcy which is, according to the first sentence, the invariable result of competition becomes in the second "a conspiracy against the public," and in the third a mere amalgamation. Be all this as it may, these dismal and contradictory forebodings need have no terrors for the consumer, however they may impress the timorous investor. Are not all these contingencies carefully provided for in the Provisional Order by a paternal Board of Trade?

Competition, like everything else, has its defects; but that it is bound to have one or other of the undesirable sequels prophesied by Mr. BALFOUR BROWNE we unhesitatingly deny; even in the case of competition in the business of electric supply, where the advantages of trade rivalry, at any rate under the conditions now obtaining in London, are by no means so obvious and overwhelming as they are in most instances. It is by no means a fair inference, as one witness argued it was, that any new company coming in must get its customers from the existing concern. If the supply of the company in possession be unreliable and dear, no doubt the major portion of the intruder's *clientèle* will be composed of ex-customers of the old concern; but they will not compose its entire *clientèle* even at first, and certainly not later on. And when, as in this particular instance, there is no allegation of an inferior supply at a superior price, experience has shown over and over again that the competitor gains his living at the expense of an entirely new set of customers and not necessarily at the expense of the pioneer undertaking. If London were apparently electrically saturated, the argument would have some weight, but things being as they are it savours somewhat of the doctrine of the old mercantile school of economists, who held that wealth was absolutely limited in quantity; so that one man's gain was of necessity another man's loss. Nevertheless, granting that competition in electric supply need not of necessity lead straight to bankruptcy, price-pooling, amalgamation or even to permanent loss to an existing undertaking, the arguments against the duplication of electrical undertakings all over the metropolis except in the quarters occupied by the much-favoured municipal enterprises, have considerable cogency. Except in the case of the upper ten thousand, who will under no circumstances take gas when they can obtain electricity, the competition of gas must be quite enough to keep down prices and stimulate economy. With nearly 1¼ million lamps connected to the London mains, it is tolerably evident that central stations already have to do with customers who *do* think of cost, and who would go back to gas for a sufficient consideration. That being so, it looks like blind fetish worship to harry electric light undertakings with still more competition, increasing at the same time the number of mains beneath our thoroughfares and adding to the frequency of surface upheavals. But then a Parliamentary Committee, especially if it be of the Lower House, is just the very body to be hopelessly opaque to any X-principle, although it will transmit to the end of time any principle which has been embodied in an Act of Parliament. To all such committees the last sentence of Section 1 of the Electric Lighting (Amendment) Act of 1888 is a sole and a sufficient warrant. "The grant of authority to any undertakers to supply electricity within any area, whether granted by licence or by means of a Provisional Order, shall not in any way hinder or restrict the granting of a licence or Provisional Order to the Local Authority or to any other company or person within the same area." Circumstances may alter cases. But nothing under heaven can alter the principles that guide (?) a Parliamentary Committee to its decisions, unless it be some dry document which has received Royal Assent one hot August day.

REVIEWS.

Elements of Electricity and Magnetism. By Prof. J. J. THOMSON. (Cambridge University Press.)

The study of the theories of electricity and magnetism, according to the method usually adopted by text-books, consists for the most part of statements of the results of research, both experimental and mathematical, with explanatory notes comparing the two. In books of this kind there are, it is true, portions of analysis to be found, but careful investigation reveals important gaps or assumptions in the chain of argument in places where the author has considered the complete mathematical treatment to be too complicated and above the heads of his readers. From a practical point of view this method has many advantages, affording to the reader a means of acquiring an acquaintance with the present state of our knowledge of the subject without requiring of him the power of checking for himself the accuracy of the knowledge obtained. In fact, it may be argued with some plausibility that it is no more necessary to follow carefully through the mathematical structure of some particular theory than it is to repeat the experimental work upon which it is based, and the shortness of life necessitates a certain amount of faith in the reliability of other workers.

Nevertheless, for the true student of science there is always a satisfaction in identifying for himself as far as possible the security of his foundations, and in tracing out the chain of reasoning upon which the various formulæ and theorems rest, while at the same time his power of using them under different conditions is vastly augmented. By such students Prof. Thomson's book on "The Elements of the Mathematical Theory of Electricity and Magnetism" will be much appreciated, as affording them access to ground which has been hitherto, in many cases, beyond the limits of their power or available leisure. In a book of moderate size the author has given the lines of reasoning by means of which the main structure of electrical and magnetic theory has been built up. He begins with the fundamental facts of electrostatics, and finally arrives at the theory of electromagnetic wave propagation, including on the way short discussions on side issues, such as electrolysis, thermo-electricity and alternating-current problems.

In a book originating from the Cavendish laboratory the treatment of the subject naturally follows Maxwell's system, but the reasoning is much simplified from the methods employed in that writer's famous treatise, and with the exception of a few paragraphs a knowledge of the elements of the differential and integral calculus is sufficient for the complete understanding of the text. It is indeed recognised now that avoidance of the calculus by the use of cumbrous algebraic proofs or verbal explanations renders a book not one whit more intelligible to beginners, and certainly makes it uselessly verbose and involved for everyone. Prof. Thomson has, however, introduced many simplifications in the mathematical treatment of electromagnetic theory, avoiding the complete investigation when it is only a particular case that is required. Though the book is not and does not pretend to be suitable for the casual reader, the comprehension of the methods employed should not prove more difficult than the appreciation of the results attained, and this is really the lowest needful limit of simplification.

A distinctive feature of the book is the frequent comparison of the physical aspect of a theorem with its mathematical treatment. Faraday's tubes of force and the action of the medium form the guiding principle throughout, and lead up

Digitized by Google

to the development of electromagnetic waves and Maxwell's theory. It is essentially a treatise on physical electricity, in which mathematical analysis is called in only in so far as it is needful, and in their clear physical interpretation of analytical results these parts of the book will be found highly suggestive and interesting to mathematical readers.

The chapters on electrostatics deal with the usual theorems, Gauss's theorem being taken as the fundamental, and many of the proofs depend immediately on this. The principle of minimum potential energy is largely employed, and the energy residing in the medium is frequently examined, thus bringing the physical idea strongly to the front. In the electromagnetic theory intimate connection is kept up with the earlier parts of the book, and the identity of many of the expressions is preserved as often as possible, thereby reducing the demands upon the patience of the reader in purely mathematical portions, and correlating similar properties in electrostatics and magnetism. In the same way the distribution of electric currents falls under the same laws as those of the force in the electrostatic problem.

The chapter on dimensions and the foundations of systems of units is exceptionally clear while it is thoroughly sound. The relation of the C.G.S. system, and the derived electromagnetic and electrostatic systems, the essential and the conventional parts of each and the variations which are possible in the latter, are treated in a masterly manner. It appears that Heaviside's system has not yet been admitted as a serious rival to the present method of measurement, since there is only the slightest notice of it in this book. It must be allowed, however, that from the point of view of the orthodox mathematical treatment his improvements do not lead to any great gain in simplicity.

It may be regretted that the space occupied by ordinary text book information on batteries, electrolysis, magnetisation of iron, and a few other points, has not been more usefully employed. The modern theories built upon these phenomena have been excluded, and the main principle of the book is not aided by this information; moreover, all readers of the book would already possess this knowledge to a much more complete extent than is given by the author; while we cannot help grudging the pages devoted to these extraneous points, and wishing that they had been devoted to a fuller treatment of Hertz's work and its extensions in the last few years. A succinct and efficient account of this branch with its connection to the other parts of magnetic theory is much needed by students, and the style of the rest of the book makes us regret the loss of the opportunity.

One point only in the book calls for some question. In the otherwise very valuable chapter on alternating currents, the usual expressions for the currents in a transformer are given, with the assumptions of sinoidal curves and iron cores without hysteresis. It is well known to every one who has ever plotted the current curves of a transformer on open circuit that these expressions are not in the least like the actual curves. While such readers will not be deceived by the formulæ, it is surely desirable in a book for students to point out the serious limitations to any mathematical treatment dependent on the assumption of the constancy of μ in iron. It is especially needful in this chapter, since there is a flavour of practical application about it and frequent reference to numerical constants which suggest that the expressions are working formulæ. It may be that a closer interpretation of the facts is not at present possible, but that only places a writer under additional obligations to indicate the conventionality of the assumptions that are made.

The book is singularly free from misprints, and the diagrams are clear and useful, those of lines of force in electromagnetic and electrostatic fields of various kinds being especially worthy of note. In the lettering of quantities in analysis there are, it must be confessed, a few unnecessary ambiguities and divergences from the usual symbols employed, but there are always clear statements of the meanings of symbols (a boon to the reader which is not always conferred by some modern writers), and frequent references to earlier sections.

When the labours of Prof. Thomson, both in the field of advanced theory and of experimental work are remembered, we cannot but be grateful to him for spending his time in making a little easier to humbler workers the thorny path to the mathematical theory of electricity and magnetism.

F. G. B.

Current from the Main. By W. S. Hedley, M.D. (London: H. K. Lewis. 1896.)

The vagueness in the title of this little book throws considerable doubt, at first, upon its purpose; but when we have examined more fully its title page and contents we find that it professes to be a treatise on "the medical employment of electric lighting currents." It is as though the purchaser of a work on "Town Water Supply" should discover to his dismay that it treated only of the use of town water in making up homœopathic prescriptions. Dr. Hedley is the medical officer in charge of the electro-therapeutic department of the London Hospital; and by his official position he is in possession of valuable special information, in regard to this growing branch of medical and surgical practice. It is not generally known, even among medical practitioners, that it is a very different matter to take current from the mains, for medical or surgical work, than to use the current given by a small battery. In the former case precautions have to be observed that do not enter into consideration in the latter instance. Dr. Hedley's little work, of some 31 pages, the greater number of which have appeared in the *Lancet*, should be read by every medical practitioner who is interested in electro-therapeutics.

HIGH VOLTAGE LAMPS AND THEIR INFLUENCE ON CENTRAL STATION PRACTICE.

DISCUSSION.

The following is an abstract of the discussion which followed the reading of Mr. Addenbrooke's Paper before the Institution of of Electrical Engineers. Speakers who have returned their remarks revised have an asterisk placed against their names:—

Thursday, March 12th.

Mr. J. W. SWAN said Mr. Addenbrooke's Paper raised the question whether the time had not come when electrical engineers might arrange their plans for general electric supply on the assumption that incandescent lamps adapted to a voltage double that now in vogue would be forthcoming on demand, and whether there was good reason to believe that lamps of that kind would be as cheap and as good as the lamps for lower voltage. It was, without doubt, a question of the greatest moment whether incandescent lamps of low candle-power, and requiring a voltage of something like 200 or 220 volts, could be made to compete in point of efficiency and cost with lamps for the lower voltage now in common use. The demand for such lamps was comparatively a new demand, and as yet it was not a large one, but it was increasing, and the pressure was already sufficiently strong to compel the most strenuous efforts to meet the demand in the way it was required to be met—viz., by the supply, at a moderate cost, of a lamp for double the voltage hitherto employed, and that should have a fairly long life at a moderate efficiency. He thought that was very nearly the way in which Mr. Addenbrooke stated the question. Mr. Addenbrooke had told them that it was already possible to buy fairly good lamps of 8 and 16 c.p. to take from 200 to 250 volts. The lamps shown appeared to bear out that statement. From his own experiments he knew that it was possible not only to fulfil the very moderate requirements stated by Mr. Addenbrooke, but to go considerably beyond them, and as time went on, the difficulties which attended a new departure of that kind would undoubtedly decrease, and the result would be both increased efficiency and diminished cost. But in the meantime it must be remembered that the 220-volt 8 c.p. lamp was a more fragile thing than the 110-volt lamp of the same candle-power as at present made, and rather more costly to manufacture. Looking at the question from the point of view of the electrical engineer, instead of that of the lamp manufacturer, it was fairly clear that these drawbacks had a sufficient, and perhaps more than sufficient, compensation in the additional facilities they gave for a wider and more economical distribution of current from supply stations, a most important advantage, and one well worth making some considerable sacrifice to gain. But he hoped the ardour for progress in that direction might not lead to the adoption of lamps requiring double the voltage of the lamps now in use in connection with already existing installations, except after the most thorough over-hauling of all portions of the installation, including the wiring of the houses. To go from the question of high voltage to that of high efficiency, the real difficulty connected with the employment of lamps at a higher efficiency in watts per candle was not so much in the lamps themselves as in the conditions under which they were generally used, both in connection with the private and public supply of current. The fluctuations of pressure to which lamps were subjected were commonly too great to give a high efficiency lamp a fair chance of life. At 2½ watts per candle the filament was, of course, heated to a very high temperature, and any rise in voltage above that which produced the 2½-watt efficiency was very trying to the life of the lamp; in fact, they all knew that even the best lamps of that character

Digitized by Google

would not bear for long any extra pressure producing a super-high efficiency and a super-high temperature. The published charts made by the recording voltmeter showed that in the case of nearly all the public electric supply companies, the normal voltage was often exceeded by more than 5 per cent., sometimes by even 10 per cent. When such pressure was brought to bear on lamps at the high efficiency of 2½ watts per candle, the result was disastrous. But given a voltage that never rose more than 1 or 2 per cent. above the normal point, there was then no difficulty in realising that degree of economy of current which Mr. Addenbrooke had described as obtainable by the use of 2½ watt lamps. Things would doubtless greatly improve in this respect, and he therefore hoped that in the near future it might be practicable to make a much more general use of lamps of high efficiency than under existing circumstances would be either convenient or economical.

*Mr. C. H. STEARN said that all interested in the extension of electric lighting could not but feel a deep debt of gratitude to Mr. Baynes for the courageous experiment he had tried at Bradford under such very difficult circumstances, and had carried through to so triumphant a conclusion. Mr. Addenbrooke, also, by his pen had rendered great service to the new movement by bringing clearly before the minds of many who had not previously given much attention to the matter, the great importance of the economical results that would follow from the general adoption of the system of higher pressure in central station practice. With Mr. Addenbrooke's view that

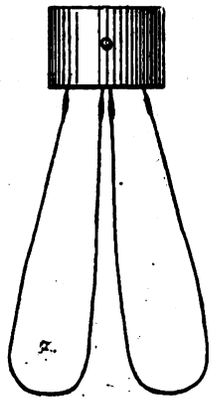

FIG. 1.—First type of High-voltage Double-filament Lamp, 16-c.p., 200 volts. ⅔ actual size.

economy in lighting could be more easily reached by high pressure and low temperature than by high temperature and low pressure, he fully agreed, inasmuch as they had not the same difficulty which the decrease in light of high temperature lamps presented, while at the same time they had, or were likely to have, a more equably maintained pressure on the lamps themselves. As to duration, he must differ from Mr. Addenbrooke in the view that increased pressure necessitated any diminished duration either in 16 c.p. or in 8 c.p. lamps. Careful experiment had shown that the duration at equal temperatures (at least at temperatures corresponding to 3·5 to 4 watts per candle) was, if the filament were homogeneous, independent of the sectional area of the filament, that is, within the limits of 1,200 to 1,400 hours. Dealing with the same efficiency in the comparative trials to which

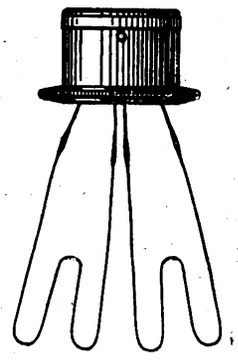

FIG. 2.—Second type of High-voltage Double-filament Lamp, 8-c.p., 220 volts. ⅔ actual size.

he referred, the lamps of 8, 16 and 6 candles at 200 volts gave similar results, that is to say the majority were not destroyed after 1,100 hours. If in commercial lamps this result was not always confirmed in the thinner filaments, that evidently arose from preventable causes. The defects in some earlier forms of double filament lamps (Fig. 1) were that they were unsuited for using out of the vertical position, as installers, though they do not expect the laws of gravity to be suspended in their favour when dealing with gas, had decided that the lampmaker must be able to so completely triumph over gravity that his lamps could be used in any position. The form (Fig. 2) shown on the board, through the greater stiffness of the filament obtained by the M form, would bear being used out of the vertical without falling and touching the glass. Some of these had run in a horizontal position for over 800 hours without any perceptible drop of the carbon. Though the double-filament lamp was, on the whole, the best as a transitional form, yet no doubt the single filament, if it could be made sufficiently rigid and self-supporting, would ultimately become the typical form. The long life, which was obtained at efficiencies of 3·8 to 4 watts, showed clearly that they could move with advantage in the direction of higher efficiency with perfect safety. But at the outset it was well to first establish public confidence in the durability at the lower temperature, and then gradually to pass on to the higher efficiency. With the construction of carbon filament suggested by Mr. Topham, shewn in the lowest row of lamps on the board (Fig. 3) low resistance carbon with its increased length could be more easily dealt with, and in that way a higher efficiency could be obtained without any increase in the rate of fall in candle-power. The movement had now gained such strength that there was little fear of its opponents being able to resist its progress. The same objections now raised as to the diminished life of lamps at doubled

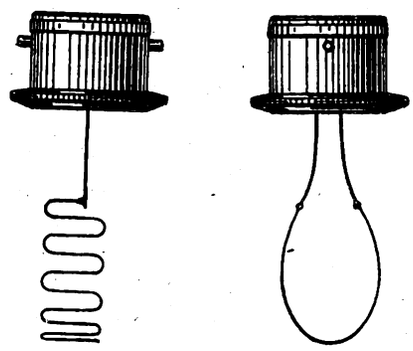

FIG. 3.—New type of High-voltage Single-filament Lamp, with Sinuous Carbon, 16-c.p., 202 volts. ⅔ actual size.

voltage were raised at the outset in 1881, when they passed from 50 to 100 volts. But for all that the 100-volt system had displaced the 50-volt, as it in its turn would be displaced by its double. The 8 c.p. and the 6 c.p. lamps of 230 volts, he ventured to prophesy, would be firmly established in popular favour this time next year, and they would all wonder why they had made so much difficulty over so simple a matter.

*Mr. T. A. ROSE said he would simply give his experience of high voltage lamps, and that was that he found very little trouble in the manufacture of them. Of course a little more care was required. Still, he had been very successful, and had supplied the lamps to several places, such as Wolverhampton, Manchester, Bradford, &c., from which places he had received very flattering reports and increased orders.

*Mr. J. F. C. SNELL said at the King's-road station, St. Pancras, the lamps were running entirely at a pressure of 220 volts. At the present moment there were about 4,000 lamps fixed, the greater number of them having been running for five months. They had had very little trouble indeed with them, and he did not think the consumers really knew the difference between the 220 and 110-volt supply. His experience caused him to think that manufacturers ought to make some difference in the cutouts and holders; it was in the holders that they got the chief difficulties. There was either short-circuiting between the contacts or between the contacts and the brass case. With reference to the life of the lamps, he had had some running at his house for over 1,300 hours. With regard to the steadiness of pressure, the Board of Trade now permitted them to vary to the extent of 3 per cent. above or below the standard pressure. On a 440-volt supply, that was a three-wire system, with 220 volts on each side of the balancing wire, the percentage variation would obviously be less than on a 220 volt three wire system, and this should conduce to the longer life of the higher voltage lamps.

*Mr. C. J. ROBERTSON said the troubles his firm had found with high-voltage lamps up to the present were practically nil, except in the case of people who had to handle the lamps in the course of manufacture. They had to use low specific resistance filaments, which were, he imagined, the only practical filaments to be used. Beyond that he pretty well agreed with what Mr. Swan and Mr. Stearn had already said. The Incandescent Electric Lamp Company, (Limited), had had very small experience, but they were perfectly capable of converting all their manufacture instantly to 200 or even 300 volts if required.

*Mr. W. GEIPEL said before he read Mr. Addenbrooke's Paper he was under the impression that, granted the 200-volt lamp was successful, it was all up with transformer systems; but if all Mr. Addenbrooke said was true, then he thought those of them who had devoted years to the perfecting of these systems might feel that there was a vast field of use still before the results of their labours. He thought they were many of them indebted to Mr. Addenbrooke, in the first place, for the care he had taken in showing them that even with the three-wire and 200-volt lamps and the station planted in the centre of the town, the low-pressure direct supply system for distributing apparatus alone cost £60 per kilowatt. He was quite sure that on the alternating-transformer system, with 100-volt lamps, this figure would cover the cost of the whole works, including buildings, generating plant, and distribution. It required no words of his to emphasise the singular importance which the first cost had upon the cost per unit. He might remind the members that they would find a curve showing this relation in his contribution to the discussion on Mr. Crompton's Paper "On the Cost of Electrical Energy" (May, 1894), in which they would see that taking a given sum for works costs the total cost per unit varied from about 3½d., when the first cost of plant was 2s. 9d. per unit sold, to 1½d. when the first cost was 6d. He thought, therefore, that if Mr. Addenbrooke's estimate was

Digitized by Google

correct the transformer system would give a cheaper supply with a 100-volt lamp than the direct system would with a 200-volt lamp. In addition to that he saw that Mr. Addenbrooke calculated his £60 per kilowatt for distributing from the centre of a town radially in all directions, so that excepting in unusual cases, there was the increased expense of working as compared with the high tension station, which might, of course, be situated more favourably. It was a matter of fact that at least one of the important direct supply stations in London had decided to remove from the centre of the district to a spot entirely outside, so that at any rate in that case they appreciated those expenses and difficulties, while Mr. Addenbrooke's calculations as to first cost presumably would in such case be increased. He did not believe, however, that the 200-volt lamp was the correct lamp to use—in fact, he quite agreed with Mr. Addenbrooke that it was in the tentative stage, and he feared it would remain there for many years to come. They all knew that, apart from all questions as to economy in watts per candle and as to the necessity of small candle-power, lamps could be made and used successfully very much higher than 200 volts, but then people could not all afford to use Sunbeam lamps in their little dark corners, especially in those places which required artificial light all day. The question to his mind resolved itself upon the 8 c.p. lamp; people ought to have the advantage of using such lamps without wasting half the energy by burning another lamp in series with it as had been suggested, for they might just as well use the 16 c.p. lamp at once. Could lamp makers produce a good 200-volt lamp of 8 c.p. which would last 600 or 700 hours with a strain of three watts per candle? His experience was that they could not do it, and he knew one of the leading makers who candidly admitted it. He doubted if it could be done at less than six watts per candle. Indeed, it was difficult enough to obtain efficient 100-volt 8 c.p. lamps which would stand, satisfactorily, the ordinary varying pressure of an electricity supply works. A great deal was made of the improvements which had taken place and which might be expected in lamps. He would be a bold man who stated that advance were an impossibility, but had that wonderful improvement actually taken place? Ten years ago good 100-volt 16 c.p. lamps could be obtained using four watts per candle and lasting 1,000 hours. It might be that the watts had been reduced to 3½ watts per candle for a similar life, but he thought that was about the extent of the improvement. Of course the price had been so much reduced that it paid to use lamps at a higher efficiency, but the improvement in the quality did not appear to be so wonderful. For his part, he thought the 200-volt lamp policy a mere subterfuge, which should be strongly opposed. Why were people adopting the Welsbach gas burner? Simply because they got a good light for half the consumption of gas. If, then, they wished to compete with the Welsbach—and it was a serious competition—they must give the consumer a lamp which took less watts; in fact, the tendency, if anything, should be to reduce the 100-volt supply rather than to increase it to 200 volts, for he thought no one would deny that with the lower voltage more efficient 8 c.p. lamps could be made. It was his opinion that the popularity of the electric light would be distinctly and unfavourably affected if they forced upon the consumer a 200-volt supply.

Mr. L. EPSTEIN said the figures as regards accumulators contained in the Paper were borne out by his experience, and he really had no fault to find with them.

*Mr. A. A. C. SWINTON said Mr. Geipel had touched on the question of efficiency, which, of course, was a very important one, but he thought it ought to be carried a step further. They were told that the efficiency was so many watts per candle. Now what did a candle mean? There were two candles: there was a foreign candle, a German candle he believed, and an English candle, and he must say that in many cases he had been much puzzled to know to what particular candle-power the makers referred.

*Mr. W. H. PATCHELL said he had not had time to read this Paper, although it had been sent out a week before, but on looking over it it had struck him as a Paper of extreme moment. There were several things in it which touched central-station practice very pertinently. He had tried for some time to introduce 200-volt lamps, but he had first tried to get the lamps at the same price as those of 100-volt. This was of manifest importance to every central-station engineer, for if he doubled his pressure the capital value of his mains was increased, but when the consumer came to pay the bill not only for current but for lamp renewals, he thought the Company would have to subsidise the consumer to some extent or find him the lamps at a loss. Whether that would pay the Company was a moot question. He thought as they had so many lamp makers present he ought to impress upon them the importance of having the price the same as for low-voltage lamps. They had heard that night of difficulties with 100-volt 8 c.p. lamps, but he had had no trouble with them when run at a steady pressure. Those who had had difficulties could not have run them on a steady pressure.

*Mr. H. W. HANDCOCK said a client of his firm had for a long time been complaining about his lamps going, and the matter was a mystery to them. At last they told him the best thing to do was to see the engineer at the central station. The result was he was advised to use 110-volt lamps instead of 105-volt. This was a little bit suggestive, as the circuit was only a 105-volt circuit. They had heard a great deal about the satisfactory life of 200-volt lamps, and the advantages of these lamps had been demonstrated to them very obviously, from the central station point of view; but they had not heard very much from the consumer's side. They should have before them relative figures. That was to say, taking a lamp of the same life if they liked, they wanted to know what was its efficiency at 200 volts, what was the efficiency of a similar lamp at 100 volts, and also what was its efficiency at 50 volts; also what was the candle-power of that lamp at each voltage at the end of 1,000 hours. In their experience they felt that with the 100 volts the limit had been about reached. Occasionally they had very good lamps, but when they went far above 100 volts they had so much trouble and such continuous complaints about filaments going that it was evident the life was very uncertain. If the voltage were steady it was quite a different thing, and he thought the inventor of the incandescent lamp had struck the right nail on the head when he spoke of the great fluctuation of pressure they were subject to at the present moment. As things were 90 per cent. of the difficulties were due to faulty lamps, and the trouble was got over in New York by the Company including in their rate the lamps themselves. Every lamp went through their laboratory and was carefully tested with the photometer; anything not coming up to their standard was rejected and returned to the makers. If they had some similar system here the gain would be very considerable. Going back to efficiency, he should like to ask this question now they had so many central station engineers present: If they doubled their voltage were they going to supply the consumer with current at such a rate that if he got the same amount of light out of his lamps his account would be the same instead of 33 per cent. more than it was now? Taking the case of three watts on the existing circuits, where an account amounted to £100, with four watts that account would come out at £130. Were the customers to expect a substantial reduction which would also cover the expense due to the higher price of the 200-volt lamps?

*Mr. W. R. RAWLINGS said if they were going to compete against gas, it was necessary to carefully consider the question of cost. He was very often called in by people who wanted to know the reason of their enormous electric accounts, and he very often found that in out of the way places 16 c.p. lamps were kept burning simply because those lamps had a long life. If they reduced those lamps to 3 c.p., such as some of the 100-volt lamp makers were giving them, and put in 8 c.p. lamps where more light was required, they would then reduce the electric account to something reasonable.

*Mr. SYDNEY BAYNES sent some remarks, which were read by Mr. J. F. C. Snell. As he believed he had had the privilege of being the first to employ lamps of high voltage in electrical distribution, a short summary of his experience might not be without interest. In early days it remained an open question whether central stations would ultimately become a source of revenue to municipalities or not. The expenditure was consequently limited and meagre in comparison with the handsome sums now freely voted by municipal bodies. Shortly after the opening of the Bradford installation in 1889, it became evident that the mains were likely to become loaded in a much shorter time than had been anticipated. It thus became a pressing question with him in what manner he could increase their carrying capacity with the smallest possible capital outlay. After carefully going into the matter, the most promising solution of the difficulty seemed to be theoretically in the adoption of a three-wire system with lamps at 230 volts. The three-wire system was already in the market, not so the 230-volt lamp. Feeling confident, however, that the lamp was but a question of time, he made ready for its adoption by giving personal attention to every detail in the wiring of premises, and prohibiting the use of double-pole cutouts, so that when the day came for the fulfilment of his expectations, there should be no cause for anxiety in connection with the consumers' premises. He could only touch briefly on the initial difficulties in procuring lamps. After persistent inquiries and interviews, he managed to procure small consignments from several makers. Only one design of lamp, however, survived the test satisfactorily at that date. After further considerable delay another firm entered the field, and supplied a good lamp; but it became apparent that to achieve any degree of success it would be necessary to encourage the manufacture of such lamps on a commercial scale, and, as he was then satisfied that two makers could be relied on, he resolved to give effect to the scheme which he had so long hoped to put into practical use. Accordingly, he issued notices intimating that all future consumers would be supplied at 230 volts. There remained the terms of the Provisional Order to consider. The most diplomatic method of dealing with the difficulties therein presented appeared to be—first, to prove the practical utility of the double pressure, and then leave the matter for the consideration of the Board of Trade. He therefore used only the outer conductors as a pair, and thus maintained the spirit of the order. He had to acknowledge his indebtedness to the Board of Trade in allowing him a certain latitude wherein he had time to demonstrate the practicability of the innovation. At an early stage in the working of the scheme he had numerous inquiries from America as to lamps and the measure of success achieved. He now learned that in the comparatively short time which had elapsed there were over 15 central stations in the United States working with 200-volt lamps. They were not yet in a position to report such progress on this side of the Atlantic—a striking instance of British caution contrasted with Yankee go-aheadness. In regard to the question of current density, he would suggest that Mr. Addenbrooke was too liberal with his allowance of copper. He preferred to allow for a 2 per cent. variation, with distributors extending 880 yards from the feeding centres, and working at a current density of about 700 amperes per square inch. The pressure should be gradually increased to 2 per cent. above the normal at the feeding point as the load approached maximum, while the pressure on the distributor at the far end would fall 2 per cent. below the normal; thus by a judicious compromise they were able to limit the variation at the lamp terminals to 2 per cent. In that way the number of feeding centres would be reduced to a minimum, and might be spaced at intervals of a mile. The generating station would feed direct into the network up to a half-mile radius; and the distance in any direction to 2½ miles would be readily dealt with by throwing out two feeders into the distance to be supplied. The near feeder would obviously be worked at double the current density, so that both the near and the far feeders would be coupled to one common 'bus bar. It would be advisable on the score of economy to serve the home position of the network from a separate bus 'bar, as the voltage would only be required to exceed the normal by 2 per cent. at maximum load. It being usual to place feeding centres where roads intersect, there would be 8 distributors, each extending 880 yards, or a total frontage of 7,040 yards. Allowing for branch streets, you might readily count on a lamp density of three lamps per yard. This would represent about 3,200 amperes at 440

Digitized by Google

volts to be delivered to each feeding point. It would be preferable to divide this current amongst four seperate conductors constituting the feeder. This method of grouping the conductors simplifies the regulation, and allows for the adjustment of varying pressures by switching off portions of the feeder should any irregularity occur between the feeding centres. The facility in regulating thus afforded would be considerably augmented by a judicious selection of the sectional areas of the cables combining to make up the feeder. Very shortly the King's-road works would be supplying current with the distributing network extending a total distance of nearly 2¾ miles to the furthest lamp. He might here remark that providing the centre wire of the distributing system be brought back to the generating station, and reasonable care taken to balance the distribution of lamps, there appeared to be no necessity for a centre feeder. In regard to the possibility of using lamps of high efficiency and low voltage, since the regulation at the increased pressure would approach much nearer the ideal than had hitherto been obtainable, those lamps could be adopted two in series, with a success and certainty which was quite impracticable on a system run at 110 volts. The tendency in shop lighting was to group several lamps on a switch. so that it would make little difference whether they were burning in series, parallel or otherwise. If a really reliable high efficiency lamp could be obtained any waste of current inevitable from the necessity of burning two in series would be a mere trifle compared with the economy effected by their use. As to lamps of high voltage, those makers who had devoted both time and money to perfecting their methods had been remarkably successful in producing lamps of comparatively high efficiency, averaging from 3·3 to 4 watts per candle, whilst the average life already greatly exceeded that assumed in the Paper. He considered the profession was under an obligation to several of those manufacturers for their persevering efforts to keep pace with the requirements of the electrical industry, and in their courteous endeavour to deal with and remedy any defects that had occurred during the development of the lamp; but for their able assistance they would not be assembled that evening to discuss that very interesting Paper. As to the question of fire risks, where the wiring had been well done there was certainly less risk than with the lower voltage, first because the fuses were lighter, and, second, because should an arc occur across the casing, the current would more readily exceed the carrying capacity of the fuse. In the St. Pancras installation they limited the current through any pair of mains to 25 or 30 amperes, and as each circuit was protected by the Vestry's standard fuses, kept under seal, it was immaterial whether or not any fuses existed on the branch circuits. The rule that no conductor should be smaller than a No. 18 S.W.G. rendered a 220-volt supply absolutely safe, though not a single branch cut-out existed on the whole system, because they might short-circuit and blow the main 30-ampere fuse through a No. 18 S.W.G. insulated conductor without damaging it in the least. Cut-outs in ceiling roses were useless; the branch cut-outs—one on each pole—with 1in., or certainly not less than ⅜in. of clear break, should be relied on. Double-pole cut-outs should not be permitted, as they were liable to short-circuit. Main cut-outs at entrance of buildings should have by preference 1¼in. to 1½in. of clear break. No trouble whatever had been experienced with any switches or other fittings. It was regrettable that the insurance companies still acknowledged the use of casing with the conductors kept at about an arcing distance apart. Practically that was wrong; the conductors should be kept in close proximity, then on the failure of the insulation, instead of an arc springing up and continuing (as he had known it to do on 115-volt circuits) a "short" would occur, at once blowing the fuses. He was unable wholly to concur with Mr. Addenbrooke's remarks as to the effect on alternating-current practice. As the most modern systems now employed a distributing network, the introduction of a higher voltage lamp would be a distinct advance for either system.

*The PRESIDENT (Dr. John Hopkinson) said as Manchester had been referred to by one or two speakers he should like to add a few words to the discussion. At Manchester, of course, they had for two or three years had experience of the high voltage; in particular, in the Town Hall they were working at 400 volts, for they took in all five wires there. According to circumstances they burned from two to four lamps in series, and they had large groups in series for the lighting of public rooms. They had had no trouble whatever in connection with the wiring. Of course they had special fuses arranged for the purpose. The question of leakage had been referred to in connection with Manchester. It was true that from the negative terminal there was a substantial leakage; and that existed, and always existed, because they were bound to put the middle wire to earth. That, of course, really arose from the fact that bare copper was used to a considerable extent. It was now used to a greater extent on account of the great facility it afforded for making connections and avoiding vulcanising of the joints. But leakage caused them no inconvenience at all; still, there was, of course, a certain admitted loss of power from that leakage. Mr. Addenbrooke had referred to the use of accumulators, and particularly to the use of accumulators at out stations, and he had pointed out that if you required to increase the capacity of a main you could do so by putting an accumulator at the end of that main and charging it. The fact really amounted to this, that comparing the out-station accumulator with the corresponding power at the station, you should compare its cost with the cost of the boiler, the engine, the dynamo, and the feeder. There was an additional advantage in the use of out-station accumulators in the fact that such great facility for regulation was obtained; they could regulate the pressure at the end of that feeder to the extent of one cell.

*Mr. G. L. ADDENBROOKE, in his reply, said that he mentioned in the paper a certain proportion of 8 c.p. lamps to 16 c.p., and, following out earlier experiences, he was under the impression that the number of 8 c.p. lamps was very considerable, but when in conversation with Mr. Swan recently that gentleman said that the sales of the 8 c.p. Ediswan lamps did not amount to much more than a quarter of the 16 c.p. lamps. That was, he thought, a very important point, because if after so many years the Edison-Swan Company, which had enjoyed almost a monopoly, had found comparatively so few 8 c.p. lamps were used, it was clear that this must indicate the proportion of 8 c.p. lamps in use, which was so small that the argument against the 200 volts on the ground of the difficulty of procuring good 8 c.p. lamps was greatly lessened in force. Was it not a pity that central-station engineers calculated all their results in 8 c.p. lamps when there was a much more reliable basis in 16 c.p.? There was one very curious thing about this higher voltage question, and that was this: Why had they not had an intermediate voltage? It was very curious that there were no 150-volt lamps in the market, for they would be very useful for lighting factories and many other purposes. He believed lamps of these voltages were much more largely used on the Continent. But apparently in this country we were going to make a big plunge right away. At Edinburgh Prof. Kennedy was changing the whole system to 230 volts, and he believed the Westminster Company were offering their customers to change their customers' lamps to 200 volts for 1s. 3d. each and to give them a certain guarantee if they would go over. He spoke without actual official data, but he fancied the Brush Provincial Company had determined to use 200 volt lamps at the Wandsworth station, and that voltage was going to be in use at many other places. Mr. Shoolbred had told him that he was carrying out the Birkenhead installation on this system, and found his calculations come very near those in this Paper. There was one thing this debate had brought out: they had actually seen the lampmakers and heard them speak. He did not think they had ever heard very much from the lampmakers since Mr. Swan first brought out the lamp, and there was no doubt a great many electrical engineers had been feeling their way in the dark to a great extent with regard to this lamp question. Mr. Swan had spoken about the fluctations of voltage: this had been a sort of pet subject of his (the speaker's) for a long time. It was very much greater in extent than central station companies liked to acknowledge, and it was one reason why up to last year he had been in favour of alternating currents, for if they were forced to use 100 volts they would get better regulation than on a continuous-current system, at any rate, if the area were at all considerable. That was a good deal altered by having 200-volt lamps. In the experience he had had of 200-volt lamps he felt sure they were a good deal less affected by slight changes of voltage than 100-volt lamps. He had recently tested some oil engines on dynamos which were not very steady, and with which they were not always able to keep the voltage down; once or twice they ran away, and caused the voltage to rise to 300 volts. The lamps were horizontal, and although some filaments were bent over, and seemed half fused, they did not give way. In one or two cases the filament touched the under side of the lamp, but in other cases it did not, but for some time afterwards burnt in the bent form. He was sure Mr. Stearn's remarks would be very much appreciated. He had made the subject a speciality, and certainly the form of lamp he had shown was exceedingly pretty, at the same time that it was a thoroughly practical form, one, indeed, which would be very nice, even at 100 volts; they got the light more concentrated. Mr. Geipel spoke of the £60 a kilowatt in his (the speaker's) estimate as the cost of distributing mains; but he had pointed out that that estimate was for a station carrying feeders 2¼ miles long, and it assumed that the density of population was the same over the whole area. As regards alternating central stations, he was told the cost per kilowatt in the case of the Islington station amounted to £21?.

Mr. GEIPEL: That includes some provision for extension.

*Mr. ADDENBROOKE said that might be. Practically he was willing to admit that that was an outside figure; but there it was. Mr. Baynes had given them some actual figures. He himself had taken a very small drop, a lower one, indeed, than Mr. Baynes considered desirable. If they wanted even pressure, which all lampmakers would tell them was necessary, they must have more copper. The amount of copper at 250 amperes per square inch came out at a very moderate figure. Mr. Baynes allowed a rather greater fall and worked at a greater current density, and, no doubt, if they worked out the central station that way, the cost of mains per kilowatt would come down very much indeed, even on the £60 which he had taken as a rough basis. Referring to a Paper read before the North-East Coast Institute of Engineers fifteen months ago by Mr. Alexander Siemens, Mr. Addenbrooke said the real object which Mr. Siemens had in writing the Paper was lost sight of. The Paper was written to show the running of the central station. It was true the central station was established at Messrs. Siemens' works, but it was a very large one. To all intents and purposes it was a central station of about 1,000 or 1,200 H.P., and that was working at something less than a nine-hours' load, the load factor being 0·28. Well, Messrs. Siemens said the result of a six months' run of that station under ordinary working conditions, the cost of their coal being 17s. 10d. a ton, and adding the cost of labour, depreciation and other matters, was that the cost per kilowatt hour came out a little over ·58d. It was true the cost of labour might not be quite so large an item as in another station, because they had skilled engineers who could attend to it; still with a load factor of 0·28 and coal at 17s. 10d. a ton, the cost per kilowatt hour was about ·58d. What Messrs. Siemens could do others could do; if they had a nine-hours' load they could generate their current for something in the neighbourhood of ½d. It appeared to him if they could introduce accumulators, which the present price admitted of, they could supply current, except for the question of distribution, and except for one or two other questions, at a very much reduced figure on its cost at present. If they could get these 200 or 220-volt lamps and cut down the cost of their mains in such a proportion, and if they could get accumulators and keep their voltage even, they might generate the energy quite as economical as Messrs. Siemens. He might say in reply to some of the speakers that in view of the great gain to companies of 220 volts, they could very well afford, where customers used them, to make a slight reduction in the cost of current, and he had shown

Digitized by Google

that a reduction of ¼d. would really cover anything the consumer was likely to suffer from. Mr. Addenbrooke concluded by saying that he would give his reply more fully in the pages of the *Journal* of the Institution.

The meeting then adjourned until March 26th.

THE BOOSTER IN RAILWAY WORK.*

BY J. B. SCOTT.

The limitations of the 500 volt direct system of feeding are very soon felt when any very large amount of travel has to be provided for at a considerable distance from the power house. Here it becomes absolutely necessary to adopt some means of cutting down the enormous amount of copper needed, if the road is to be practicable from a financial standpoint. To take an actual case: In laying out the feeder system of the City and Suburban Railway, of Baltimore, the following conditions had to be met. The general plan of the system shows six main branches radiating from approximately the centre of the City, on the south water front. It was determined to locate one main power house at this point, for besides being the centre of the system, it had exceptional facilities for receiving coal both by water and rail, and gave an unlimited supply of water for condensing. Several of the lines extend from five to seven miles from this point, and have a very large summer excursion travel to the parks located at the ends. To handle this occasional load satisfactorily by the direct feeder system at such distances would have required an enormous outlay of copper. The extremely heavy load is only felt on Sundays and holidays and warm nights during about four months in the year. At these times there are as many as 20 cars on each suburban division, while for the remainder of the year but two or three cars are required.

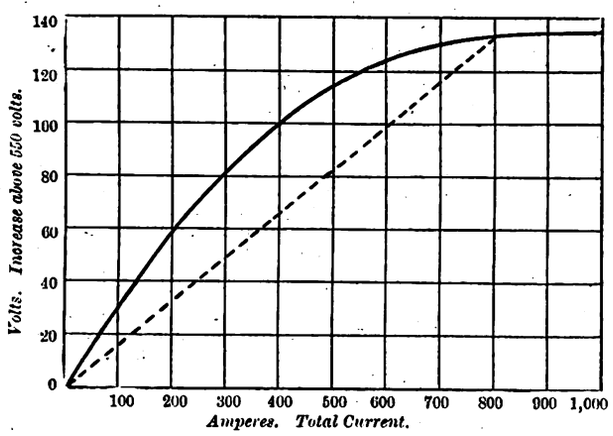

FIG. 1.

Under these conditions the booster seemed especially suitable, and was accordingly installed, with sufficient copper in the line for the ordinary travel up to six or seven cars, with a drop of 50 volts by the direct feed. The ordinary shunt-wound booster used in lighting work was not considered suitable for this purpose, as it would have required constant attention to regulate the voltage by hand on the variable loads experienced in railway work. To accomplish this automatically the fields were wound with series coils only. This gives a regulation which, while not theoretically perfect, is entirely satisfactory for railway work. The curve in Fig. 1 is plotted from readings taken from the machine in actual service, and shows the variation from the theoretically perfect regulation indicated by the dotted line. The greatest variation from this is at 400 amperes, where it amounts to 35 volts, this being only a trifle over 5½ per cent. of 615 volts, the normal for that current in this case. This is negligible in railway work.

The machine used in this case was a standard General Electric Company's six-pole lighting generator, with a capacity of 800 amperes and 125 volts. The field coils were rewound for series connection, and the machine was belted to an auxiliary engine already installed for running a 200-kilowatt standard railway generator. This generator is used for lighting the cars and barns, and also for shifting cars after the road is shut down at 1:30 a.m. As the two machines are thus used alternately, no additional engine plant was required. The remainder of the plant at present consists of four 500-kilowatt standard railway generators.

The switchboard connections, in simplified form, are shown in Fig. 2; but for convenience the circuit is run through a special panel, similar to the usual generator panel, but with only an ammeter, voltmeter and circuit-breaker on it. A quick break switch is placed in front of the machine to cut it entirely clear of the circuit when necessary, but the double-throw switches on the feeder panels are generally used for throwing the machine in circuit. From the main 'bus bar the circuit is through the circuit-breaker and ammeter to one side of the machine, through the armature and field and switch to an auxiliary 'bus bar on the long distance feeder panels. By throwing any switch up, the feeder is connected directly to the main 'bus bar at 550 volts. By throwing the switch down, the circuit is completed through the booster. If the heavy loads on the different feeders do not occur at the same time, one machine can be made to serve for a number of feeders, but if the heavy loads occur simultaneously, it is preferable to have a separate machine for each feeder, though in an emergency two or three feeders can be thrown on one machine, up to its full current capacity, but without the advantage of automatic regulation of voltage.

The accompanying table shows what may be done with this particular machine on various distances. With higher voltages, longer distances may be economically fed, though, of course, the operating expenses and first cost of the machine would be somewhat greater. The results in the table, however, only show what has been actually accomplished with a machine in regular service. The first column shows the distance required to be fed, for simplicity a trunk line, without distribution. Columns 2 and 3 show the amount of copper required for the various distances when the drop is respectively 175 volts and 50 volts, with a load of 675 amperes. Column 4 shows the actual amount of copper saved by allowing the additional 125 volts drop in the line. Column 5 shows this saving expressed in dollars, the copper being taken as worth $550 per mile erected, not including pole line. Column 6 shows the cost of the booster, including foundation, belt and switchboard panel, this cost being constant for any distance in this particular case. Column 7 shows the saving in first cost between the booster

* Abstract from the *Street Railway Review* of Chicago.

† [This is a wire approximately 0·46in. in diameter, or about 19/12.—ED. *E.*].

Digitized by Google

for 175 volts drop and the additional copper required for the direct feed at 50 volts drop. This saving in first cost is itself sufficient to recommend the system to a large class of railway managers who, from necessity or otherwise, consider a dollar saved in the equipment worth two in the operating expenses.

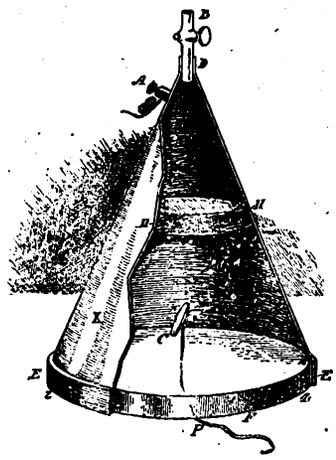
But the next three columns show the real value of the booster in railway work. Column A, when operating 10 hours continuously during the year, shows a loss between the saving in first cost and the capitalised cost of operating expenses for a shorter distance than 7 miles. Column B, when operating 10 hours a day for four months in the year, shows a gain from a little over 4 miles and upwards. Column C, representing Sunday travel during the summer and early fall months, shows a decided gain at 2 miles, while at 5 miles the saving in first cost is over 10 times the capitalised cost of power.

In making the above comparisons the cost of power is taken at 1 cent per kilowatt-hour, including fuel, water, labour, interest and depreciation of plant, and is a fair figure for an ordinary plant. At 675 amperes and 125 volts this amounts to $8.40 per day, which capitalised at 5 per cent. per annum for the number of days in operation, gives the amounts in the columns.

It is only necessary to add that the machine is in every way satisfactory to the management of the road, having been in operation since July, 1895.

A NEW FORM OF RAY LAMP.*

We illustrate herewith a new form of ray lamp devised by Prof. Woodward, of Harvard University, by means of which excellent radiographs have been obtained. As the sides of the lamp permit cathode rays to pass through them, the fact that with it radiographs may be obtained contradicts the theory that a glass envelope plays an essential part in the generation of Röntgen rays.



From the diagram it will be seen that this new form of ray lamp is that of a cone, and its characteristic difference from the ordinary Crookes tube is that the sides or walls of the lamp, H H, are made of sheet aluminum, $\frac{1}{10}$th of an inch in thickness; the base of the lamp 1, 2, 3, 4, is of solid glass, practically a plug fitted into the base of the aluminum cone with plaster of paris, and made air tight. A metallic ring passes around the base of the cone at E E, and holds the sides of the cone firmly to the glass bottom. Through a point, F, a little to the side of the centre of the glass base, passes the cathode pole into the lamp, and at the end of this is fastened a platinum disc, at such an angle as to be parallel with the side of the lamp at the point X. At the top of the lamp, and directly connected to the metallic side, is the anode pole A, and at the top of the cone is a glass tube with a stop-cock, so that the air may be exhausted. This glass tube is also fastened in with plaster of paris and bound by a metallic ring. A circular wooden disc is fastened on the inside of the metallic cone at H H, to prevent any collapse of the sides on exhaustion. By this construction it has been found that the difficulty from the absorptive power of the rays by the glass of the Crookes tube has been eliminated in a most marked degree.

Fluorescent Salts.—An American firm of chemical manufacturers has announced that, owing to the extraordinarily large demand for barium platino-cyanide, "they have been obliged to increase their laboratory force."

* From the *Electrical World* of February 29, 1896.

PARLIAMENTARY INTELLIGENCE.

THE STRAND DISTRICT ELECTRIC LIGHTING ORDER.

On Friday last, at the House of Commons, Sir J. Kitson's Committee on the Electric Lighting Provisional Orders (No. 4) Bill resumed the consideration of the Strand District Electric Lighting Bill, which had been sent down by the House of Lords' Committee. Mr. Pember, Q.C., Mr. S. Wills, Q.C., and Mr. Claude Bagally appeared for the promoters. The Metropolitan Electric Supply Company (Limited) petitioned against the Bill, and were represented by Mr. Balfour Browne, Q.C., and Mr. Fitzgerald, Q.C. The promoters' case was reported in our issue of the 20th inst.

Sir James Kitson, the Chairman of the Committee, was unable to be present, and his place was taken by Mr. C. J. Murray, the senior member.

Mr. BALFOUR BROWNE, in opening for the petitioners, said one of the most important principles that had been submitted to a committee of Parliament was now before the committee; that was whether there was to be complication in electric lighting. He was going to ask them to come to the conclusion that competition in electric lighting was not in the interests of the public, and if the Committee agreed with him he trusted they would reject the Provisional Order. Why should the Order be confirmed? He would show the Committee absolutely that the alternating-current was as good as the direct for the purposes of power. The promoters suggested that competition would bring down prices. It was, of course, to the interest of the public to have electricity supplied as cheaply as possible, but the question was, would competition bring down prices more than regulation. He absolutely denied it. The prices of the Metropolitan Company were fixed by an agreement between the Company and the Strand District Board of Works entered into seven years ago. According to that agreement a revision was to take place every seven years, so that this year the revision would take place, and the interests of the public would be fully protected. The highest price the Company could charge was 7½d., while the highest price which the Charing Cross Company sought to be able to charge was 8d. The promoters said that the real advantage of competition was the reduction of price, but that reduction could be secured without competition. The only parts of London where competition could be tried were the only parts where it ought not to be allowed. The Strand was the very part of London where the breaking up of the streets caused the greatest inconvenience, and because it was a rich part companies like the Charing Cross Company wished to come into it. It was certain that by one means or the other the public would have to pay more for the two installations than for one. That had been established again and again. Although competition in gas was possible yet it was not encouraged by Parliament, because it was found to be bad for the public. If there were two mains in one street where one would do the consumer had to pay more for his gas, and in the case of repairs the streets had to be taken up twice instead of once, and thus the public was inconvenienced. Where competition was allowed between two companies in one district it almost invariably resulted in the bankruptcy of one of the companies. Competition between such companies inevitably led to combination, and combination was nothing but a conspiracy against the public. If this bill passed the result would probably be that either the Metropolitan or the Charing Cross Company would become bankrupt, and the surviving company would have to buy it up and then charge higher prices to recoup themselves. If the local authority in course of time desired to buy up the existing rights, they would have to buy up two companies instead of one. It was therefore no wonder that the District Board, by 17 to 8, desired to rescind the consent they had already given. It had been suggested that the Board had been influenced in some way, but no evidence of this had been given.

Mr. GEORGE LIVESEY, examined by Mr. Fitzgerald, said he was a member of the Institution of Civil Engineers and Chairman of the South Metropolitan Gas Company. Witness deposed that in the case of gas companies experience had shown that in the great majority of instances, where competition was allowed, there was first an arrangement as to price, and then amalgamation between the companies.

Cross-examined by Mr. S. Wills, WITNESS said he was aware that the local authority had the power to revise prices every seven years whether there was combination between companies or not. In electric lighting, if Callender cases were used, there was very little occasion for breaking up the streets. He did not think that electric lighting companies needed any competition to keep down the price other than that supplied by the gas companies with their cheap gas and their improved burners. In the public interest it was certainly desirable that more companies should not be allowed to occupy the streets than was absolutely necessary.

Prof. SILVANUS THOMPSON, examined by Mr. Fitzgerald, said there was no difficulty in using the alternating current for even the largest motors, and as a matter of fact the largest motors were used with those currents. Motors of several hundred horse-power could be run with them as well as small motors. The advantages of alternating-current motors were several. He thought it was a fair inference that any new company coming in must get its customers from the existing company. He was positive on the point that there was no difficulty in using alternating currents for any of the ordinary purposes of arc lighting.

Cross-examined by Mr. Wills, Prof. THOMPSON said he did not think that the continuous current was better for small motors. For supplying power to a large factory it was probable that three-phase alternate motors would be used. For smaller requirements in the Strand the Metropolitan Company used one-phase motors. Some few years ago there was a difficulty experienced in starting the motors, but modern improvements had removed that.

Mr. FRANK BAILEY, examined by Mr. Fitzgerald, said he was chief engineer to the Metropolitan Electric Supply Company, and engineer to

Digitized by Google

the City of London Electric Light Company. There was no doubt whatever that all the fair requirements of the Strand district had been met by his Company, for they were able to supply electricity to any person who wanted it. If any of their customers wished for continuous current the company were ready to give it. Last year some gentlemen living in the district gave evidence before the House of Lords Committee, when they stated they were desirous of getting a continuous current. Witness stated at the time that his company were prepared to supply it, but not one of them had applied for it. It was believed that it was the intention of the Charing Cross Company to establish their new works at some distance from the area of supply. It would be impossible, if the works were so situated, to give an adequate supply of electricity throughout the Strand District by the continuous-current system. Communications had been received by the Metropolitan Company from customers of the Charing Cross Company complaining of the character of the light supply to them.

Cross-examined by Mr. S. Wills, WITNESS said he had cursorily looked through the books and he had seen the names of half a dozen of their customers who had motors which were driven by the alternating-current.

Mr. ARTHUR VENTRIS, engineer to the Strand Board of Works, was the next witness called. Mr. Wills raised the objection that the Strand Board had given their consent to the Provisional Order, and were not appearing against the Bill.

Mr. BALFOUR BROWNE said Mr. Ventris would be examined in his individual capacity. He appeared on the Speaker's Order.

The WITNESS said that on January 30, 1895, he made a report to his Board on the state of things which would exist in the district if the Provisional Order were confirmed. In it he referred to the fact that the streets and pavements would be cut up and permanently disfigured, and expressed the view that in some streets it would be almost impossible to find room for new mains.

Cross-examined by Mr. Wills, WITNESS said he had not obtained permission from the Strand Board to attend and give evidence, nor was the Board aware that he was coming. He was not aware that after the receipt of his report the Strand Board approved the Provisional Order.

A report prepared by Mr. Crompton, an electrical engineer who was consulted by the Strand Board, was put in and read by Mr. Fitzgerald. The report condemned the proposal of the Charing Cross Company.

Mr. DE FERRANTI said there was no difficulty in supplying motors with the alternating current. On the question of competition he was able to speak with some experience. Competition between electric companies was bad for the companies themselves, and did not lead to economy so far as the consumers were concerned.

This closed the petitioners' case.

The room was then cleared while the Committee consulted in private.

On the public being readmitted, the CHAIRMAN intimated that the decision of the Committee was that the Order, as amended, should be confirmed.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 13th, 1896.*

The Westinghouse-General Electric Combination.—It is officially reported that the General Electric and Westinghouse Companies have finally come to an arrangement in regard to the common use of patents. The basis of the agreement is that the General Electric Company's patents shall be valued at 62½ per cent., and those of the Westinghouse Electric and Manufacturing Company at 37½ per cent. of the value of the combined patents, and each company is licensed to use the patents of the other company, a royalty being paid for any use of the combined patents in excess of the value of its contribution. A Board of Control is to be in charge of all matters relating to patents, and will consist of five members, two appointed by each company, and a fifth selected by these four. These negotiations have been under way at intervals for more than a year, but heretofore no agreement could be reached, the high value placed upon the polyphase patents having been, it is thought, the cause. In passing it may be noted that the negotiations from the beginning have been a considerable source of profit to insiders through manipulation of the stock market. Each time the negotiations were resumed there was an advance in stock, advantage of which was taken. In the present instance, the General Electric stock, which a few weeks ago was quoted at 30, advanced to 40.

Contributory Infringement.—A recent Federal Court decision, based upon the lately-sustained Van Depoele trolley patent, holds that a manufacturer infringed that patent who sold trolley stands, one of its elements. The Court implied that parts, such as the trolley wheel pole, or others having a short life, can be supplied by others than the patentee, but the stand is such an essential part of the overhead running trolley that the owners of the patent alone could supply it, even for repair purposes.

Rapid Transit for New York.—The construction of the municipal underground rapid transit road in New York city seems now to be assured. This week the Commissioners appointed by the State Supreme Court, which Court possessed a veto power over the measure, reported in favour of the project after having heard most voluminous testimony both for and against it. During the sitting of the Commission no other motive power than electricity was referred to by the various experts examined. Mr. Frank J. Sprague, and Mr. David L. Barnes of the Westinghouse-Baldwin combination, both advanced systems of electric traction for adoption. That of the former consists in each car having its own motors, either one or two, all to be controlled from a single point in the train. The plan of Mr. Barnes proposed the use of electric locomotives.

CORRESPONDENCE.

RÖNTGEN RAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is accepted as a fact that "the X-rays discharge negative electricity from all bodies with great rapidity, and positive more slowly, leaving every body finally with a positive charge."

I have just discovered that this law is not true, and that the correct statement is as follows:—

> The X-rays charge some bodies positively and some negatively, and whatever charge a body may receive by other means the X-rays change it, both in magnitude and in sign, to the charge which they independently give to the body.

Thus, while gold, silver, copper, platinum, iron, &c., are all charged *positively* by the X-radiation, I find that sodium and magnesium are charged *negatively* and with much greater effect than any of the above metals. Of course, we find also that if a positive charge is given to magnesium the X-rays instantly discharge it and replace it by a negative one, and that they merely diminish or increase a negative charge given to the metal. Antimony is almost neutral; but, apparently, it belongs to the positive group. Doubtless we shall now find a number of bodies behaving like magnesium.

It seems, then, that this observation disposes of the theory (which I held and worked on until yesterday) that the X-radiation is a stream of electricity (or electrified particles) shot off the Crookes tube. These positive and negative effects seem to bring the rays under the category of waves, the result being just the same as that which ordinary light gives with various kinds of photoelectric cells.

The result is greater with a bright surface than with an oxidised one.

I shall give a full description of the experiment later. Meanwhile observe that inductive effects from the coil and Crookes tube on the electrometer must be carefully screened off.—Yours, &c.

Cooper's Hill, March 24, 1896. GEORGE M. MINCHIN.

[ADDENDUM] Many metals are charged negatively by the rays. The following is a list of metals arranged in approximate descending order of their susceptibility to positive and to negative electrification:—

Positive.	*Negative.*
Iron.	Sodium.
Platinum.	Magnesium.
Copper.	Tin (greatly depending on surface).
Steel.	
Aluminium.	Lead.
Gold.	Zinc.
Bismuth.	
Silver.	
Antimony.	

Antimony is very feeble. The behaviour of tin is just the same as that with ordinary light. Sodium is very strong, and must be charged with negative electricity to a high degree before the rays begin to diminish the charge.

THE CLARK CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to your correspondent "X" in your last issue. In the first place, owing to the article in question having been hurriedly written and proof not corrected, there are several mistakes and omissions; for instance in the phrase cited, it should have read that the Board of Trade adopted "the Clark cell as a *commercial* standard for the comparison of E.M.F.," the writer being quite aware of the definition of the true standard. As to the advisability of the Board's so doing, whether they should or should not, is of course, a matter of opinion; but there are few *practical* men who hold the negative view, and unless the writer is mistaken their ranks are not likely to be thinned by the article in question, which article "X" must have skimmed over very lightly, or "it" would have noticed that the writer mentioned that cells *had* been made according to the Board of Trade specification; in fact, one such cell takes a prominent place amongst the experiments given.

With reference to "manipulative skill and general laboratory experience," the writer addressed Dr. Muirhead upon these very points, and was assured that they had absolutely nothing to do with the construction of a reliable cell, and as a proof stated that he had set a man from his workshop, who had never seen a cell made, to make up several dozen from the raw materials. This he did with perfect success, the cells in no way differing from those made by the usual assistant.

In conclusion, the writer would only add that he is not so optimistic as not to look forward with pleasure to the prospects of a definite one-volt standard cell.—Yours, &c.,

WM. C. FISHER.

Crompton Laboratory, Thriplands, Kensington Court, London, W., March 24th.

THE AUDIT OF ELECTRIC LIGHTING ACCOUNTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As one interested in electric lighting undertaking I should like to make a few remarks upon the article in your columns of March 13th, "The Audit of Electric Light Companies' Accounts." I consider the object of the Board of Trade audit is to see that nothing is put to capital that can in any way be charged to annual income. The Memorandum of Association of most of the electric lighting companies naturally give them extremely wide powers, such as to manufacture engines, the purchase of lands, &c., and companies could under the memorandum embark in business of a very speculative nature, but the Board of Trade will not permit this. They naturally wish that at the end of 42 years the local public should have the opportunity of acquiring these industries on the lowest possible terms, and the less the capital expenditure so much the better for the public, as no one is likely to value the industry at more than the capital expenditure (except under very exceptional circumstances). As a consequence the Board of Trade are very stringent in making electric light companies write down items which the companies' auditors hold are fair charges against capital. For instance, I heard of a case the other day in which directors' fees paid during the construction of buildings and works were not allowed by the Board of Trade as a capital charge, although the directors had during the period of construction more onerous duties, and the charge is quite as just a capital one as architect's and engineer's commission.

It appears to be maintained by your article under reference that the Board of Trade desire lighting companies to have as good an annual income as possible, having in view the reduction of the rate per unit at the septennial average, but this I hold to be quite an erroneous idea. The companies have in many instances voluntarily reduced the rate nominally 8d. to an average of 5½d., and largely increased their profits thereby, so that it is evidently also the companies' interest to work at as low a rate per unit as possible, and this is quite a secondary consideration to the reduction of capital charges.

The Board of Trade auditor is, I consider, a most unsuitable person to audit the accounts of an electric lighting undertaking for the shareholders. However unprejudiced he may desire to be, he has a natural bias for his employers the public, and the economy of fifty guineas or so is, in my opinion money ill saved. As I have shown, it may result in many thousands of pounds, fair capital charges, being charged against revenue to the shareholders' loss and the public gain.—Yours, &c.,

March 21, 1896. OBSERVER.

LEGAL INTELLIGENCE.

Wake v. H. Calhaem and Wake v. E. E. Calhaem.

These actions were recently heard at the Lord Mayor's Court, London, and were brought by the plaintiffs, Messrs. Sanders, Wake and Co., the well-known mica merchants and shipbrokers, who sought to recover damages from the defendants, formerly clerks in the plaintiffs' service. Plaintiffs' counsel stated that the defendants were brothers, and had been in the service of the plaintiffs for some years. This action was brought to recover damages for breach of duty in improperly disclosing the names and addresses of the plaintiffs' customers, to recover any notes or memoranda now in their possession belonging to the plaintiffs, and also for an injunction restraining them from using information obtained from the notes and memoranda. Whilst in the plaintiffs' service the defendants gained experience in the mica business, which was only carried on by six firms in London. While in the plaintiffs' employ they disclosed to another firm in the same business the names and addresses of the plaintiffs' customers, and other valuable information. The consequence was that the plaintiffs' had lost some valuable contracts, and a mass of evidence in support of this part of the case was given. Two cases were especially referred to as glaring instances of the unscrupulous conduct of the defendants, and of the singlar methods by which certain persons in the mica trade obtain business.

Mr. B. B. WAKE, the senior member of the firm, stated that his firm had received an apology from the defendants, and he estimated the damages at £250. The defendants denied that they interfered with the plaintiffs' customers in any way.

The learned RECORDER observed that one of the defendants had pleaded infancy, but he should tell the jury that was not a valid defence if they did what they were charged with doing. Ultimately a private consultation took place between the learned Recorder and counsel, and defendants' counsel consented, on behalf of his clients, to a verdict for the plaintiffs for £10, an injunction and costs, which terms were accepted. The plaintiffs, taking into consideration the position of the defendants, and the fact that they were young men just starting in life, decided to forego costs. The learned Recorder said he thought defendants' counsel had adopted a very wise course, having regard to the practical confession of the two youths. There was no doubt that an impudent attempt was made to undercut the plaintiffs in their business, and he was not sure that the plaintiffs might not have taken a much more serious course, as there was such a crime known as conspiracy. He thought Mr. Wake was a kind-hearted and generous man in not pressing for costs, as, if he chose, he could make either one of the defendants bankrupt. He had been not only just, but kind and generous.

Reduction of Capital.

On Monday last the Manchester Edison-Swan Company (Limited and Reduced) applied to the Vice-Chancellor of the Lancashire County Court for the sanction of the Court for a further reduction of capital. Mr. Tweedale, who appeared for the petitioners, said that in 1887 the capital of the Company was reduced from £600,000 to £550,000, and a resolution had now been passed for a further reduction to £300,000. This was to be effected by extinguishing the liability in respect of uncalled capital to the extent of £4 per share. His Honour sanctioned the proposed reduction, and continued the use of the words "and reduced" in the title of the Company for one month longer.

Poole and White (Limited) v. South.

In the City of London Court, on Friday last, Mr. T. Ellis, the receiver and manager of Poole and White (Limited), sued Mr. Harry South, for the recovery of £37. 7s. 10d. for electrical fittings supplied. The action was remitted from the High Court. The claim was for electrical switches and holders supplied from July, 1894. The defendant had filed a counter claim for electrical appliances and fittings supplied for an allowance for returns, and for a special allowance on 620 lamp holders. The defendant also claimed 2½ per cent. on the sum of £115. 13s. 11d., the value of goods supplied to the plaintiffs. The defendant admitted the plaintiffs' claim less £5. 12s. charged for a switch which he alleged had been returned. The plaintiff also admitted the counter claim, except as to £25. 4s. 4d. In the end the Assistant Registrar found for the plaintiffs for £17. 10s. 10d.

BOOK RECEIVED.

"Synopsis of Current Electrical Literature," 1895. By Max Osterberg. (London: Messrs. Kegan Paul, Trench, Trübner and Co. Price 5s.)

Digitized by Google

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d. abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations.

TENDERS INVITED.—The Directors of the Lancashire and Yorkshire Railway require tenders for the supply of various stores for the twelve months ending April 30, 1897, of which some particulars are given in our advertisement columns, and further particulars and forms of tender can be had at the Stores Department, Osborne-street, Manchester, where samples are also to be seen. Tenders addressed to the Directors of the Company must be lodged with Mr. C. W. Bailey, Secretary, not later than 10 a.m. on Monday, April 6th.

——— The Electric Lighting Committee of the Derby Corporation require tenders for the supply and laying of low-tension cables and junction boxes in the borough. Plans may be seen after Monday next on application to Mr. J. E. Stewart, engineer at the Electric Lighting Station, Derby, and specifications obtained. Tenders have to be sent in to Mr. H. F. Gadsby, Town Clerk, at the Town Hall, not later than 12 (noon) of Monday, April 13th. Some further information is afforded in our advertisement columns.

——— The Urban District Council of Wallasey require tenders for (*a*) steam alternators, switchboard and accessories, (*b*) high and low tension concentric cables, and (*c*) transformers. Copies of specification can be had of the engineer, Mr. J. H. Crowther, Gas and Water Works, Great Float, near Birkenhead. Tenders must be sent in to Mr. W. Danger, clerk to the Council, Public Offices, Egremont, Cheshire, by 4 p.m. of Monday, the 6th April. Our advertisement columns contain further particulars.

——— The Edinburgh Corporation invite tenders for the wiring of the police cells. Specifications, &c., can be obtained at the offices of the resident electrical engineer, Mr. E. W. Monkhouse, 5, Dewar-place, and tenders must be sent in not later than 10 a.m. on April 11th, to the Town Clerk, Mr. Thomas Hunter, W.S., Town Hall, Edinburgh. Further particulars appear in our advertisement columns.

——— Our advertisement columns contain particulars of a concession for 50 years for the electric lighting of a town in the south of Spain, regarding which information can be obtained of the British Consul at Puerto de Mazarron, Murcia, Spain.

——— The proprietors of the Prince of Wales Hotel, Harrogate, York, invite tenders for the electric light installation (about 400 lights), including generating plant; also for telephone and bell work. Some further particulars will be found in our advertisement columns, and specifications may be obtained of Mr. Walter Leake, 30, Victoria-buildings, Manchester, to whom tenders under seal are to be sent by April 7th.

——— The Shoreditch (London) Vestry require tenders for engines, dynamos, switchboards, instruments, street lamps, pumps, steam and water mains, water tank, cast-iron work, motor transformers, starting switches, a battery of accumulators and stands. Tenders to Dr. H. Mansfield Robinson, Vestry Clerk, by 4 p.m. on Tuesday, April 14th.

——— The Electric Light Committee of the Bedford Corporation invite tenders for the supply and erection of one 240 B.H.P. double-acting compound enclosed engine, and one 150-unit alternator with stationary armature. Tenders to Mr. T. S. Porter by April 4th.

——— The Bradford Corporation invite tenders for the erection of the building work for their new electricity station. Tenders to the Town Clerk (Mr. W. T. McGowen), Town Hall, Bradford, by April 8th.

——— The Elberfeld Direction of the Prussian State Railways requires tenders for the supply and erection of the plant (including four steam engines, four dynamos, 174 arc lamps, &c.) required for the electric lighting of the railway stations of Elberfeld and Barmen. Tenders to the Königliche Eisenbahn Direction, Elberfeld, by April 20th.

——— The Municipal Council of Lima (Peru) invite tenders for the establishment and working of an electric lighting installation in the squares and streets of the city, with power to work the private service, under a contract for twenty years. Particulars may be obtained at 13, Comeragh-road, West Kensington, W.

TENDERS INVITED.—Tenders are invited for the supply of the necessary plant for the electric lighting of the County of Antrim Lunatic Asylum. Tenders to the Secretary of the Board of Control of Lunatic Asylums, Custom House, Dublin, by May 1st.

TENDERS ACCEPTED.—The Hammersmith Vestry have decided to accept the tender of Messrs. S. Z. de Ferranti (Limited) for the supply of necessary plant for their proposed electric supply station at £12,302. 1s. The original tenders were submitted to the consulting engineer (Mr. A. H. Preece), and he recommended the Vestry to adopt the alternating current transformer system. Mr. Preece also reported that, although Messrs. Siemens Bros. and Co.'s tender was the lowest, it would be more economical to adopt Messrs. Ferranti's system, and recommended that both firms should be invited to submit revised tenders for complete station plant, leaving the mains to be dealt with later. These revised tenders have now been sent in, and Mr. Preece recommends the acceptance of Messrs. Ferranti's tender.

——— The Brighton Town Council have accepted the tender of Messrs. Willans and Robinson for supplying and erecting a 750 I.H.P. steam engine coupled to a Crompton dynamo at the Corporation electricity station for the sum of £4,655.

——— The Hampstead Vestry has accepted the tender of Messrs. Sir W. A. Rose and Co. for the supply of dynamo oil, &c., for their electric lighting station for one year.

——— The tender of the Colombo Gas Company has been accepted for lighting the Galle Face Hotel, Colombo (Ceylon), electrically. Tenders were also received from Messrs. Johnson and Phillips, Boustead Bros. (Colombo), B. Verity and Sons and the Brush Company. It is also intended to supply current for lighting the bungalows in the neighbourhood of the Hotel.

TENDERS RECEIVED.—The Town Council of Durban, Natal, received eight tenders for the supply of the machinery and plant for their proposed electric supply station, viz.:—

Electric Construction Company (*accepted*, subject to modification)	£15,007	0	0
Goddard, Massey and Warner (Nottingham)	23,926	0	0
British Thomson-Houston	20,057	3	0
J. G. Statter and Co.	17,904	0	0
Wigston Electrical and Engineering Company	17,360	0	0
Brush Company	16,365	0	0
Siemens Bros. and Co.	16,350	0	0
Crompton and Co.	15,001	16	0

Only two firms—the Telegraph Manufacturing Company, of Helsby, near Warrington (£6,114), and the India Rubber Company (£5,442. 14s.)—tendered for the supply of the cables. In our issue of the 13th inst. we gave the names of the successful tenderers for the supply of the arc lamp columns and cast-iron conduits.

APPOINTMENTS VACANT.—The Bolton Corporation invite applications for the appointment of borough electrical engineer. Salary £300 per annum. Applications must be sent in to Mr. R. G. Hinnell, town clerk, Town Hall, Bolton, by April 6th next. Further particulars appear in our advertisement columns.

——— The Council of the County Borough of West Ham invite applications for the post of electrical engineer, with a commencing salary of £300 per annum. Our advertisement columns furnish some further particulars in regard to the experience, &c., required, and applications must be sent to Mr. Fred. E. Hillery, Town Clerk, Town Hall, West Ham, by 5 p.m. of Wednesday, April 8th.

——— The Staffordshire County Council require a Science Master capable of conducting classes in physics and chemistry at the Technical Schools, Stafford. Salary £200 per annum. Applications to the Director of Technical Instruction (Mr. T. Turner), Stafford, by April 25th.

STEAM PLANT FOR SALE.—Particulars will be found in our advertisement columns of a quantity of steam plant, in good condition, for disposal, on application to Mr. Dunn, Bank Lodge, Scarborough, Yorks.

PATENTS SPECIFICATIONS.—Those interested will find in our advertisement columns particulars of an application to amend Patent No. 2,329 of 1892, granted to Alfred Imray for "Improvements in processes and apparatus for bleaching by Electrolysis." Objections must be lodged within one calendar month from March 11th current.

DISSOLUTION OF PARTNERSHIP.—The partnership of Charles Richardson and Edward Geisler Herbert, electrical engineers, of Cornbrook Park-road, Manchester, has been dissolved. Debts by Mr. E. G. Herbert, who continues the business in his own name.

REMOVAL.—Messrs. Bergtheil and Young give notice of removal from 13, Walbrook, to 12, Camomile-street, Bishopsgate-street, London, E.C.

NEW FIRM.—Messrs. Ashton, Frost and Co. (Limited), engineers, of Blackburn, have added a dynamo and motor department to their

Digitized by Google

business. Mr. F. J. A. Matthews, formerly of Rosing and Matthews, Bradford, has been engaged to take charge of this department. The firm will make for the trade only.

AGENCY.—Messrs. Fleming, Birkby and Goodall (Limited), of Halifax, have appointed Mr. J. E. Lawler, of 36, Lime-street, E.C., London representative.

BANKRUPTCIES.—The following are some of the principal creditors under the deed of arrangement by Walter Emmott lately trading as an electrical engineer under the style of Walter Emmott and Co., at 16A, Thomas-street, Halifax :—

Northern Electric Wire Company	£53	0	0
B. Verity and Sons	24	0	0
Manchester Edison-Swan Company	18	0	0
Beecroft and Wightman	11	0	0

The liabilities amount to £1,197. 14s. 10d., assets £225. Mr. W. D. Taylor, Town Hall-buildings, Halifax, is trustee.

——— The Shropshire County Court has approved a proposal to pay a composition of 7s. 6d. in the £ in the bankruptcy of G. J. Reakes, electrical engineer, lately trading as G. Reakes and Co. at Shrewsbury.

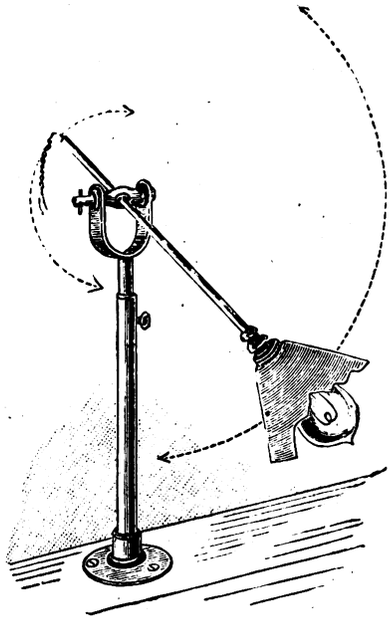
——— Notice is given of the release of the trustee (Mr. G. Wreford, Bankruptcy Court) in the bankruptcy of Walter Andreae, electrical engineer, lately trading as Walter Andreae and Co.

——— The examination of Wm. Gray, electrical engineer, lately trading as the Scottish Electrical Engineering Company, and Gray and Son, takes place at the Court House, Edinburgh, on the 31st inst., and a meeting of creditors at Messrs. Romanes and Munro's, 46, Hanover-street, Edinburgh, on April 8th.

LIQUIDATIONS.—It has been decided to wind up the Weybridge Electric Supply Company (Limited) voluntarily, and Mr. J. S. Lobb, 11, Queen Victoria-street, E.C., has been appointed liquidator.

——— At a meeting on the 16th inst. it was resolved to wind up the Coventry Electrical Engineering Company (Limited), and Mr. S. T. Peirson, 17, Hertford-street, Coventry, was appointed liquidator. On the 10th inst. Mr. Peirson was appointed by Mr. Justice North to act as receiver and manager for the debenture-holders.

ELECTRIC LIGHT STANDARD.—Mr. G. Stegmann has just brought out a useful invention for the workshop, in the form of a telescopic standard, having at its upper end an adjustable socket for the reception of a tube carrying the wires and an incandescent lamp. The socket is so arranged that the light may be brought down close to the work, as shown in the illustration, or can be turned round



in any direction. If desired, the tube carrying the wires and lamp may be withdrawn from the socket, and the light used under the bench. These standards should prove servicable to students using the microscope, and to those requiring an adjustable light.

STANDARD MEASURING INSTRUMENTS.—Messrs. Nalder Bros. and Co., of 16, Red Lion-street, Clerkenwell, London, forward an advance copy of their new ammeter catalogue, in which will be found illustrated and described the firm's latest (1896) type of ammeter. This is a brass-cased instrument, and takes the place of the "Ironclad" ammeter, being supplied at the same price. The new instrument has been designed to meet the large demand for a low-priced instrument to match ordinary switchboard work ; it is therefore felt to be unnecessary to continue the manufacture of the well-known "Ironclad" type. The list also contains useful particulars of the Preece-Trotter portable photometer (for measuring illumination and candle-power in streets, public buildings, &c.), the Trotter bar photometer (for measuring candle-power of glow lamps), and also of Crawley's patent automatic accumulator switch, the prices of which have been reduced somewhat. We are asked to point out that the letters "N. C. S." upon instruments of Messrs. Nalder Bros. and Co.'s make represent the words "Nalder, Crawley and Soames," the members of the firm, and not the "Nalder Construction Syndicate," as the letters have, we are informed, been erroneously interpreted.

PHOTOGRAPHY.—Many of our readers are interested in matters photographic, and they may like to know that a handy and useful catalogue of photographic materials has just been issued by Messrs. Ross and Co., of 111, New Bond-street, London, W.

SMOKING CONCERT.—Members are reminded that the last smoking concert of the season of the Electro-Harmonic Society takes place this (Friday) evening at the St. James's Hall Restaurant, Regent-street, W., at eight o'clock.

CONCERT.—The members of the Electrical Trades Union hold a concert, under the auspices of the London Central Branch, at the Clerkenwell New Town Hall, to-morrow (Saturday), at 7.30.

ASYLUM LIGHTING.—The work of installing the electric light at the Purdysburn Asylum, Belfast, has just been completed. The generating plant consists of two continuous-current E.C.C. machines, coupled direct to two Bumsted and Chandler single-crank engines. A battery of E.P.S. K17 cells has also been installed, the switchboard being supplied by Messrs. Crompton and Co. For lighting the various parts of the building 10 32 c.p., 90 16 c.p. and 150 8 c.p. Ediswan incandescents are employed. The work has been carried out by Mr. W. H. Drennan to the specification of Mr. V. A. H. McCowen, the Belfast borough electrical engineer.

BELFAST.—A meeting was held last week at Belfast to consider the desirability of constructing an electric tramway between Belmont, a suburb of Belfast, and Holywood. A resolution in favour of the scheme was unanimously passed, and a subscription list was opened to meet preliminary expenses, &c. A further meeting will be held this (Friday) evening.——The Borough Electrical Engineer, Mr. V. A. H. McCowen, is preparing a report on the proposed extensions of the electric light works, to be presented at the next meeting of the City Council.

COMPANIES' ACTS AMENDMENT BILL.—The *Statist* is a journal which has consistently advocated certain amendments to the Acts relating to the formation of joint-stock enterprises, and in its last issue deals with the Bill which has recently been introduced into the House of Lords. The journal points out that the vexatious 38th section of the Act of 1867 is to be repealed, so that the objectionable waiver clause which figures so conspicuously in some of the more unblushing samples of the promoter's handiwork, will be missed should the Bill become law, as every contract and fact which is material in influencing the judgment of a prudent investor must be clearly set out in detail, or the prospectus will be void. A director will, under the Act, be liable to a penalty of £5 a day if he acts without having qualified himself within the specified period of one month at most. A minimum subscription is to be set out in the prospectus, and unless this amount is reached no allotment is to be made, and no waiving compliancy with this section of the Act will be allowed to be mentioned in the prospectus. A somewhat drastic clause is that which insists upon a return of the number and amount of shares allotted, and the names and addresses of the allottees to be sent to the Registrar within seven days after allotment, or in default every director to be liable to pay £50 a day. The prospectus of a new company must be filed with the Registrar on or before publication, and must be signed by every Director and official. The statutory meeting is to be held within one month from the date of filing the declaration required for commencing business, and seven days before the meeting a report must be sent to every shareholder, giving particulars of the allotment and the cash received in respect of shares, and other information. On examination of the clauses of the Bill we find that it provides for the filing of all information concerning the creation of debentures and similar priority stock. This is, perhaps, the most important feature of the Bill. It is reasonable to look forward to a heavy flotation of joint-stock companies prior to the Bill (should it be passed) coming into effect.

CARDIFF.—The Electric Lighting Committee is again in trouble. Last week it was the question of the four fitters at the supply station ; now it is the acceptance of a tender for lamp pillars from a "non-unionist" firm. The Committee recently decided to let this tender to Mr. D. Evans, Eagle Foundry, Llandaff, but the Moulders' Trade Society protested against this, and the matter was in due course debated in the Council Chamber. The Committee

Digitized by Google

were compelled to reconsider the matter, and the contract has been transferred to Mr. Franklin Jackson, of Cardiff.

CHELSEA (LONDON).—The Vestry have decided not to oppose the application of the Chelsea Electricity Supply Company for a Provisional Order for lighting the western portion of the parish.

CONFERENCE ON LONDON GOVERNMENT.—At the recent conference between the London local authorities and the County Council the clerk of the Shoreditch Vestry (Dr. H. Mansfield Robinson) raised the question of giving the vestries power to construct tramways. He drew a vivid picture of what his own vestry would be prepared to do in running electric tramcars within its own parish, but the proposal did not meet with support.

ELECTRIC TRANSMISSION OF POWER IN MINES.—Under this title Messrs. Siemens and Halske of Berlin have just issued a brochure giving some information with regard to the application of electricity in mines, and also a record of plants manufactured by them and at present in actual operation. In the introductory part a short review is given of the different systems employed for transmission of power, and the various advantages which electricity offers over steam, compressed air, and hydraulic pressure for this particular kind of work are set forth. The efficiency of electric transmission of power, it is stated, can always be kept within reasonable limits, on an average from 75 to 80 per cent. Of the different systems prominence is given to continuous current and three-phase alternating current, and nearly all mining machines described and illustrated can be adapted to either current. Three types of three-phase motors are manufactured by Messrs. Siemens and Halske, viz., machines with three collecting rings for use with starting apparatus, machines with closed armature winding, and without collectors, and machines with a special winding and a starting mechanism. With regard to the application of three-phase current for traction work Messrs. Siemens and Halske assert that continuous current is best suited, as the former requires three overhead wires, "the use of the rails as a conductor being excluded, iron conductors not being permissible for alternating currents." This assertion does not appear to correspond with actual practice, as at Lugano a tramway is worked by three-phase currents, two trolley wires being employed and the rails making the third conductor. Various illustrations of electric mining pumps, hoists, winding machines, rock drills, and locomotives at present at work in different mines in Germany, Japan and South Africa furnish many useful hints for those interested in mining work.

——— The *Financial News* of the 24th inst., dealing with the subject of mining at Barbertown, in the Transvaal, stated that at Moodie's Fortuna Mine it was proposed to substitute steam power for the electric power now being used for the battery. According to the report of the Directors of that Company, it has been found that electric power has not proved suitable; but no figures are given in support of this view. Commenting upon this article, Mr. W. B. Esson writes to our contemporary, pointing out that its remarks might be taken by the uninitiated to amount to a condemnation of the use of electric power in gold mining. Mr. Esson contends, however, that power transmitted electrically can be made as reliable as power obtained by any other means, steam included, and he points to the success of the electric installation at the Sheba Mine as convincing proof of this. Applied to the exigencies of gold mining it has, of course, been found that certain details require to be modified as the work proceeds, but respecting the final results, so far as the Sheba Mine is concerned there has been no question. Mr. Esson concludes:—"Electric power is transmitted through cables five miles long, and the mill works night and day, never stopping save for an occasional examination of the machinery at the generating or receiving end of the lines. For the four months ended February 29th the mill worked night and day, with stoppages aggregating in that time only one day and a half in all. This amount of stoppage was made up of a quarter of an hour here and twenty minutes there to take up a belt, adjust a rope, examine a bearing, or to give to the plant any of the little attentions always required from time to time by running machinery. The record as it stands, forms an undeniable tribute to the success of power transmission by electricity, and it will be obvious that what has been done at Sheba can be done elsewhere, if the problem be tackled in the right manner."

ESTON (YORKS).—At the last meeting of the District Council the surveyor (Mr. T. W. Stainthorpe) stated that since the last meeting he had prepared and sent out to electrical engineers plans and particulars of the present system of street lighting, and several firms had expressed their intention of sending in estimates, &c., for lighting the streets electrically.

FAREHAM.—Matters are smoothing down here, and now that the Local Government Board has sanctioned the loan of £6,681 for electric lighting purposes the Local Council seem disposed to promote good feeling and to turn their serious attention to electric lighting matters. It has been decided to retain the services of the existing staff and to purchase or hire such additional plant and machinery as may be required.

FOLKESTONE.—After a long discussion the Town Council, on Tuesday last, decided to transfer its Provisional Order, when obtained, to a company to be formed.

HAMMERSMITH (LONDON).—The Law and Parliamentary Committee of the Vestry recommend that sanction be given to the United Tramways Company's Provisional Order.

HULL.—The Borough Electrical Engineer (Mr. A. S. Barnard) has prepared a report on the proposed extension of the electric lighting works. He recommends that 14,670 additional yards of mains should be laid in various streets; that it might also be desirable to lay mains in certain streets in the eastern part of the town. The Committee considered this report at their meeting last evening.

HUYTON.—Major P. Cardew, R.E., held a Board of Trade inquiry on Wednesday last into the application of the British Insulated Wire Company for a Provisional Order for the districts of Huyton-with-Roby, Whiston, Rainhill and Eccleston. The District Councils of Huyton and Whiston oppose the application, and the inquiry was held for the purpose of taking evidence. Mr. Sydney Morse, who appeared for the applicants, stated that they already possessed powers, and were actually supplying current for public and private lighting in Prescot, and also for lighting Knowsley Hall. They were prepared to spend £10,000 at once, without risk or cost to the ratepayers. Opposition was taken on the grounds that the present application did not differ in any way from the one previously refused by the Board.

INTERNATIONAL HORSELESS CARRIAGE EXHIBITION.—We are asked to state that there will be no charge made for space at the Motor Car Exhibition to be held at the Crystal Palace from May to July, and, except for attendants, who are to be provided by the exhibitors, there will be absolutely no charge. There is a road distance of eight miles in the grounds of the Palace for trials of horseless carriages exhibited. The whole of the central nave and eastern and western corridors and courts are to be appropriated to coaches, carriages, and accessories. A uniform charge of £5 is to be made for each carriage or vehicle coming under the heading of trade exhibits, and accessories will be charged for at a small sum per square foot, according to position. The Lord Mayor will open the exhibition on Saturday, May 2nd, in State. Historical exhibits from the Coachmakers and Coach-Harness Makers Companies and the Institute of British Carriage Manufacturers will form a feature of the exhibition, which will be divided into 12 sections, section 11 being devoted to the historical and modern exhibits of steam, electric, petroleum and other traction plant. Under section 12 will be included all kinds of self-propelled passenger vehicles. Competitions have been arranged for the vehicles in this section in speed and general efficiency in actual work, and facilities are to be afforded exhibitors to show their motors in actual operation in boats and launches upon the lakes and basins in the grounds of the Palace.

LARNE.—A scheme has been formulated for the construction of an electric tramway between this town and Cushendall. The promoters hope to eventually carry the line to Portrush, so as to connect it with the Bushmills and Giants' Causeway electric tramway.

LECTURE.—Mr. J. C. Howell gave a lecture to the members of the Llanelly Intermediate and Technical College at his works at New Dock, Llanelly, last week. Prof. Viriamu Jones, who was present, remarked, in proposing a vote of thanks to Mr. Howell, that there was not another establishment in Wales where such a series of interesting electrical experiments could have been performed. The lecture was illustrated by lantern slides.

MEVAGISSEY.—This quaint little Cornish town can now claim to be quite up-to-date in the matter of public illumination, for on Wednesday last it celebrated the formal inauguration of the electric light. The Mevagissey Electric Light Company placed the contract for the work with Messrs. Veale and Co., of St. Austell, who completed the job in six weeks. The contractors have also undertaken the management of the station for three years under a guarantee. The supply station is situated near the new quay, and current is obtained from a Crompton dynamo driven by a Davy-Paxman steam engine. A battery of 60 Epstein cells with a 300 ampere-hour capacity has also been put down. The street lighting (at £48 per annum) is effected by means of 32 16 c.p. and two 32 c.p., and the harbour is to be lighted by means of one 100 c.p. and 11 16 c.p. incandescents. Current to private consumers is to be supplied at 6d. per unit.

MOSS SIDE.—The Board of Trade have revoked the Collier-Marr Telephone and Electrical Manufacturing Company's Provisional Order for this district.

OFFICE LIGHTING.—The new offices of the Jewish Board of Guardians in Widegate-street, Bishopsgate-street, which were formally opened on Sunday last, are lighted throughout electrically.

OLDHAM AND HYDE ELECTRIC TRAMWAY.—Major Marindin held a Board of Trade inquiry at Audenshaw on Friday last concerning

Digitized by Google

the proposal to construct an electric tramway between Oldham and Hyde. Messrs. Sydney Morse and S. Sellon represented the British Electric Traction (Pioneer) Company, and the Town Councils of Ashton and Hyde, and the District Councils of Denton and Audenshaw, were also represented. Mr. Morse stated that the total length of the proposed tramway was seven miles six furlongs, and nearly all the local authorities through whose districts the proposed tramway would pass had already approved the scheme. The Audenshaw Council, who had received a proposal from the Manchester Carriage Company, opposed the construction of the tramway.

PAISLEY.—The Town Council have decided to establish municipal electric supply works at a cost of £25,000. A portion of the old prison buildings will be utilised as a site for the station.

PORTSMOUTH.—At the last meeting of the Town Council the Electric Lighting Committee recommended that a special committee be appointed to open negotiations with the local tramway company for the purchase of their undertaking. The Chairman of the Committee (Alderman Ellis) made a lengthy speech in support of the recommendation. He stated that the tramway company had applied to Parliament for power to introduce the overhead system of electric traction on their lines, and he had no doubt that, subject to the approval of the Corporation, their application would be granted. His proposal was that the Corporation should purchase the plant and equip the lines electrically, and then lease them to the present Company at a rental of ½ per cent. over and above the amount the Corporation would have to pay as interest to the sinking fund. They had sufficient power at the electricity station to run all the cars in the town, and at present their engines were working during the day with no profit. He was sure that if the Corporation adopted the scheme they would be able to hand over between £4,000 and £5,000 a year to the borough funds, and, in addition, they would be able to materially reduce the working expenses. After a short discussion the report was approved.

SOUTH AFRICAN EXPORTS.—Under the classification "Electrical," goods to the value of £2,897 were exported to South Africa for the week ended 14th inst., made up as follows:—Cape Town £1,117, Algoa Bay £153, East London £1,346, Natal £281.

SOUTHAMPTON.—At the meeting of the Town Council on Wednesday last it was decided to form a special Electric Lighting Committee to deal with all matters relating to the purchase of the Southampton Electric Light and Power Company's undertaking, and the electric lighting of the Borough.

STRAND (LONDON).—A House of Commons Select Committee on Friday last passed the Bill confirming the Provisional Order granted to the Charing Cross and Strand Electricity Supply Corporation authorising the supply of electric current in the area of the Strand Board of Works. The Bill was opposed by the Metropolitan Electric Supply Company, who already possess an Order for and supply current in the district. The Bill has now received the sanction of both Houses.

SUNDERLAND.—Mr. H. Tulloch, M.I.C.E., held a Local Government Board inquiry at Sunderland on Friday last into the application of the Town Council to borrow a further sum of £16,000 for electric lighting extension purposes. Evidence in support of the application was given by the Town Clerk, who stated that £25,000 had already been borrowed in connection with the Council's electric lighting scheme.

TELEGRAPHIC FACILITIES.—The Postmaster-General was present on Wednesday at the annual meeting of the Association of Chambers of Commerce of the United Kingdom, and was able to take part in a discussion upon a resolution asking for increased telegraphic facilities, and that the Posts and Telegraphs of the country should be considered as one undertaking in order to avoid the invidious comparison now made as to the remunerative or unremunerative working of the two departments. The Duke of Norfolk stated that, as regarded telegraphic facilities at railway stations, the Department were perpetually urging this matter upon the railway companies, with the result that considerably extended facilities had already been given. As regarded the period of three minutes allowed for trunk line telephonic communication, this length of time had been fixed after very careful and prolonged investigation and calculation, and had been adopted by the International Telephone Union. He could not therefore hold out any hopes of its being modified. So far as combining the Post and Telegraph Departments in one whole, he considered it would be a mistake, as it was, in his view, essential that the country should know the departments of the State that were profit-earning or otherwise.

TELEPHONIC COMMUNICATION FOR FARMERS.—A Paper was read last week at the meeting of the Fife Farmers' Club, in which a Mr. Longmuir recommended the extension of the telephone to rural districts, claiming that farmers and growers generally would by this means have more direct access to the markets of the country, and so, with increased light railway facilities, become in touch with those able to dispose of their products at higher rates than at present prevailed.

TORQUAY.—Last week, at the annual meeting of the Torquay Gas Company, the Chairman (Mr. Kitson, J.P.), in referring to the action of the Town Council on the electric lighting question, said "their old friend, the electric light, had been a long time trying to get a footing in Torquay, and if it was now shortly to succeed it would seem rather on the principle of 'now or never' than on its own intrinsic merits, or on the strength of the convictions of those who were championing its cause." Mr. Kitson, unlike most chairmen of gas companies, seems to have taken a rather liberal view of the effect of the introduction of the electric light on the prospects of his Company. He pointed out to his shareholders several towns where the only effect of the competition of the electric light had been to increase the consumption of gas.

TRAIN LIGHTING.—The Great North of Scotland Railway Company are making some experiments in train lighting, and one of their trains has just been fitted up for the electric light. Each carriage is provided with a generator and an accumulator, power being obtained from the revolving axle of the carriage.

WORCESTER.—The Market Hall was lighted electrically for the first time on Tuesday evening last by means of ten 2,000-c.p. arcs suspended from the roof. The installation has been carried out by a local wiring contractor, Mr. J. F. Santonna.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

March 9, 1896.

5,253. S. O. COWPER-COLES. London. Improvements in or connected with the electro-deposition of metals.

5,574. A. S. SMITH, T. A SMITH, R. J. SMITH, S. SMITH and T. DEAKIN. Birmingham. Improved apparatus for the electro-deposition of metals.

5,295. J. A. SEAVERNS. London. Improvements in arc lamps.*

5,298. A. J. BOULT. London. Improvements in electric flash-light apparatus. (W. Bruns, United States.)*

March 10, 1896.

5,315. E. H. SEDDON. Manchester. Improvements in the method of and means for electrically dispatching parcels from one station to another.

5,320. J. H. PARSONS. Leicester. An improved method of attaching the terminal wires to the zinc rods or cylinders of electric batteries.

5,345. R. HOLIDAY and J. FREEMAN. Barnsley. Improvements in gramme ring armatures.

5,389. H. F. JACKSON. London. An improved system of call suitable for use with autographic telegraph apparatus. (H. Etheridge, United States.)

5,408. W. S. SMITH and W. P. GRANVILLE. London. Improvements in telegraphic relays.

March 11, 1896.

5,467. E. H. HACKETT. Halifax. Improvements in appliances connected with electric tramcars and tramways.

5,479. A. S. FRAZER. London. Improvements in alternating current electric motors for operating commuting devices for converting alternating into continuous currents and other purposes.

5,480. W. V. HUNT. London. An improved method of and means for locating leakages on systems of electric conductors.

5,491. SIEMENS BROS. AND CO. (LIMITED). London. Means for varying the speed of asynchronous alternate current motors. (Siemens and Halske, Germany.)

5,506. P. F. RIBBE. Liverpool. Improvements in electric accumulators.*

5,511. W. J. DAVY. London. Improvements in arc lamps.

March 12, 1896.

5,537. G. HYVERT. Brussels. Automatic telegraph apparatus.

5,584. A. COEHN. London. Improvements relating to the use and treatment of carbon in electro-chemical or electrolytic processes, and to apparatus therefor.

5,616. A. E. PEYRUSSON. London. Improved electrolytic processes and apparatus.

March 13, 1896.

5,673. A. S. ELMORE. London. Improvements in apparatus for refining metals by electrolysis. (J. O. S. Elmore, India.)

5,703. A. J. BOULT. London. Improvements in arc lamps. (W. B. Joiles and E. H. A. H. R. von Nollendorf, Austria.)*

March 14, 1896.

5,752. J. PERRY. London. Electric apparatus for use either as an electro-motor or as an electricity meter.

8,072. WÜRL and NOVOTNY. Phonographs.

8,810. SIEMENS BROS. AND CO. (Siemens and Halske). Indicating value of electric resistances.

14,262. KARN and PAYNE. Electric signalling apparatus.

24,172. IWANOWSKI. Galvanic batteries.

1896.

207. THOMPSON (Electric Arc Light Company). Arc lamps.

1,427. MARCUSE. Telephonic apparatus.

COMPANIES' MEETINGS AND REPORTS.

Direct Spanish Telegraph Company (Limited).

The forty-fourth ordinary general meeting of this Company was held at the offices, Winchester House, Old Broad-street, on Tuesday, under the presidency of Mr. Edmund Etlinger.

The MANAGER (Mr. Charles Gerhardi) read the notice calling the meeting and the minutes of the last meeting.

The CHAIRMAN: Gentlemen, before commencing the actual business of the meeting I wish to express my great regret—in which I am sure you will all join—that our Chairman, Sir John Pender, has been and is still seriously ill. He is quite unable to attend to business. We can only hope that it may please God to restore him to health soon, so that we may see him again among us. You will probably take the report as read, as usual. In the first paragraph you will see that the year 1895, with which we are now dealing, has been on the whole not an unfavourable one. I might almost say it has been a prosperous one. We have earned sufficient money after deducting not only the ordinary expenses of working the traffic, but some rather heavy extraordinary expenses, to enable us to recommend a dividend of 10 per cent. for the whole year on the Preference shares and a dividend of 4 per cent. for the whole year on the Ordinary shares. You will remember that in each case half of this dividend was paid to you last October as an interim distribution in respect of the six months ending June 30th; and a resolution will presently be submitted to you declaring a similar dividend for the second half of the year. As regards the receipts, you will find in the second paragraph of the report that they have exceeded by £4,571 those of the year 1894, but it is only right to say that this comparison is not quite a fair one. 1894 was not only a poor year for us as far as the traffic was concerned, but I may say it was an exceptionally poor year, and therefore I have worked out what the result would be taking the average receipts for the last four years—the years 1891, 1892, 1893, and 1894. Our receipts for the year 1895, I find, only exceeded that average by £1,400 odd, and I think I am justified in saying that that excess of £1,400 is not entirely owing—perhaps only owing to a very small extent—to ordinary trade. You are all aware that there has been throughout this period a serious insurrection in Cuba, which, of course, has brought a large amount of traffic over our wires. I do not wish by any means to make you believe that we have not been as prosperous as we ought to have been, but I wish to guard you against supposing that this increase of £4,571 in the traffic receipts represents an enormous activity in trade between here and Spain, because that is not the case. Then I come to the third paragraph, in which we state that the ordinary working expenses are £238 in excess of those of 1894. This also wants a little qualification. The ordinary expenses include what we may call the working of the traffic from one place to the other, and the fixed expenses connected therewith. They have increased by this small amount of £238, and that is almost natural owing to the great increase we have had in our traffic, which means extra stationery, &c., besides some overtime done by the clerks. On looking at the accounts you will find that in addition to the excess of £238 in the ordinary expenses of working the traffic, an amount of £1,953 for extraordinary expenses has been charged. Those extraordinary expenses are composed of several small items to which I need hardly refer—an increase of income tax, an item owing to the opening of stations at Liverpool and Manchester, and a charge of £96 for expenses in consequence of the change in the representation of the Company in Spain. You are aware that our esteemed representative in Spain died, and we had to replace him. There is also an item of £151 for the removal of the offices at Barcelona and an extension of underground line. That outlay arises from the fact that we are bound by our concession to follow the Spanish Government Office. The Spanish Government built a new office or took a new house, and we had to move into it, which necessitated the laying of half a mile of underground line. These are all small items. The heavy item is the damage to the Bilbao cable in 1894, which cost £1,660. Those who were present at our meeting last year are aware that in 1894 a steamer fouled our cable outside of Bilbao, the cable being, in fact, hacked to pieces. We brought an action against the owner of the ship and it went against us. We then appealed, and the Court of Appeal sustained the judgment of the Court below. That was a misfortune for us, for we lost £1,660 by it. Still, one good thing has been done by this action for our future, and for the future of all submarine companies who may possibly get into the same trouble. At the trial it came out that the owner of the ship against which we brought our action got its anchor, in dragging, entangled with two cables. One was ours, and the other was probably an abandoned cable of the Spanish Government. Both cables were dragged up to the surface, but the lighter of the two got disengaged from the anchor and disappeared, while as regards the other cable, which we say was ours, they could not get rid of it, so they cut it and severed it. The sea was very rough at the time. We could not prove to the satisfaction of the Court which cable was ours; but the important part of the judgment is in a passage which I will quote. It says, "In the course of some time one or other of these cables goes—about that there is no question—and the remaining cable is undoubtedly cut. Now, if we were satisfied that the cable belonging to the plaintiffs (that is, our Company) had been cut, we should be of opinion that the captain had done that which he was not entitled to do, and that the defendants were responsible for the injury so caused; but I am not satisfied upon the evidence that the cable of the plaintiffs was cut." That is the whole point, I take it, on which we lost our case. I suppose it will be possible for hundreds of ships to anchor and never drag up two cables at the same time again, and I take it that in the future, if a ship, fouls a cable, and those in charge of the vessel deliberately sever it the owner of the ship is liable, the duty of the captain, according to the Law, being to slip his anchor and gear and charge the cable company with the cost. That seems to be what is established by this decision. We have a curious example of it already. A small ship—a fishing smack—fouled our cable outside Falmouth. When he found that he had fouled the cable he let go everything. He slipped all his gear and ran to Falmouth. He asked us to pay the damages, which we did, as that was the right course for him to follow. The next paragraph in the report deals with the fact that the Company's cables and landlines in connection with them have continued in good working order throughout the year. I have nothing to say on that except to congratulate ourselves on the fact. The next paragraph deals with the unfortunate loss which the Company has sustained by the death of Señor Don Jose Aparicio, who was our representative in Spain from the first inception of the Company 24 years ago. We have all known him personally to some extent, and I think that the whole of the Board and the manager agree with me that we have every cause to be grateful for the services which that gentleman rendered to us. In his place we have appointed Señor Don Vicente Coromina, who, as far as we can judge, is a gentleman very much of the same calibre. He is thoroughly acquainted with Spanish matters generally, and is a complete master of all business connected with telegraphy. We feel sure that he will do as well for us as the late Mr. Aparicio. The next point alluded to in the report is the election of Directors, which will come on presently. I have now only to refer to one further matter in connection with the balance sheet. You will remember that two years ago we informed you that the harbour authorities at Bilbao had occasion to build a new pier, which necessitated our taking up our cable, removing it beyond where they built the pier, landing it at the new place, and connecting that place by an underground line to the old place. We held that the Harbour Board, or whoever was responsible for those works, had to refund us what we spent in consequence. Last year I told you we were going on with the matter in Spain, and that I hoped it would soon come to a conclusion. If, however, law is slow in this country, it is vastly slower in Spain. We are where we were in this matter, and we can only await the result. If the case goes against us, we have the satisfaction—if it is a satisfaction—of knowing that we have long since paid for this work, so that it cannot make our position worse, while if it is in our favour it will make a difference in the accounts, as the amount in question will be transferred from one side to the other in the balance sheet. I now move—

"*That the report and accounts now presented be and are hereby received and adopted.*"

Mr. JOHN DENISON PENDER seconded the motion.

Mr. E. S. PEARSON observed that a good many balance sheets came before him, but none were presented in a more admirable form than that which was submitted to the shareholders of this Company. There were two very satisfactory features in the accounts, namely, the increase of £4,500 in the revenue, and the addition of £5,000 to the reserve fund, which now stood at the substantial amount of £28,000. The investments of the reserve fund were also very satisfactory. He presumed that the debenture redemption account of £19,000—he referred to the last item but one on the debit side of the balance-sheet—was not really a liability, but, he hoped, was more in the nature of reserve fund.

Mr. M. B. COCHRAN inquired where the case alluded to by the Chairman was tried—the action for the breakage of the Bilbao cable.

The CHAIRMAN: In the Court of Admiralty in this country.

Mr. COCHRAN said he understood that the breakage occurred near Spain.

The CHAIRMAN: The vessel was an English ship, and the case had to be tried here.

Mr. COCHRAN thought the legal expenses, £9, very moderate, and he therefore wished to know whether the expenses connected with the trial were included.

The CHAIRMAN: That expenditure is included in the sum of £1,660. We are gratified that Mr. Pearson is satisfied with the balance sheet which we have taken every pains to make clear for our shareholders. With regard to the item of £19,069 for debentures redeemed, the entry states—"being amount taken from reserve fund towards the redemption of £62,000 6 per cent. debentures in May, 1894." What took place was this. We were indebted to the amount of £62,000 in debentures at 6 per cent. We thought we could do better than that,

Digitized by Google

and we issued new debentures at 4½ per cent. At the same time we did not see any good in renewing this £62,000, as we did not want the money. We therefore took a certain amount from the reserve fund and a certain amount we got from the call of £1 a share; but what we took from the reserve fund was £19,000. You can easily put it on the other side of the account by taking it off the value of our cables, but there is no reason for that, so it stands on the debit side as a liability, but it is a liability to you, that is, if the Company were wound up to-morrow, and you got £141,847 for your cables, &c., you would not only get 20s. in the pound for your shares, but this bonus in addition of £19,000. It is a liability, but, as I have said, it is a liability to yourselves. It is not represented by cash. I am very glad you made your remarks, because I made a omission in my opening observations. I ought to have said that we were able to pay these dividends after transferring £5,000 to the reserve fund, and, of course, after providing for the debentures.

Mr. COCHRAN desired to know how the traffic returns were being maintained, as he believed the information would be interesting in view of the present position of Cuba. That island had been in a state of chronic insurrection for the last 30 years, but the present was certainly the most serious outbreak the Spanish authorities had had to deal with. From private sources he heard that a very large portion of the crop would this year be valueless. He was told that not one-third of the tobacco crop would be obtained, and the information as to the sugar crop was very indefinite. He thought that this would materially affect the Company's operations.

The CHAIRMAN: The returns this year have been extremely favourable. What you say is perfectly correct. No doubt if there is an insurrection in the country trade must be affected. There is, however, a very large trade between Cuba and the American States, and commerce in that direction will probably suffer more than in the direction of England.

The CHAIRMAN then put the motion, which was carried unanimously. Continuing, he proposed the payment of the dividends recommended.

Mr. PENDER seconded the resolution, which was carried unanimously.

On the motion of Mr. JOHN GLOVER, seconded by Mr. E. S. PEARSON Mr. Etlinger and Mr. Pender, the retiring Directors, were re-elected.

The auditors, Messrs. Deloitte, Dever, Griffiths and Co., were afterwards re-elected.

An extraordinary general meeting was held subsequently to consider a resolution altering clauses 90 and 91 of the articles of association.

The CHAIRMAN, in moving the resolution, stated that there were only three Directors, and at present two went out of office every year. This had been found perfectly unnecessary, and, he might almost say, irksome. He believed the Company could be carried on perfectly well if they followed the course usually adopted by companies by which the directors retired in the proportion of one out of three.

Mr. COCHRAN seconded the motion, which was carried unanimously. Mr. Cochran afterwards proposed a vote of thanks to the Chairman and Directors. He expressed sincere regret at the absence of Sir John Pender, and an earnest hope that that gentleman would speedily recover.

Mr. STIMPSON seconded the motion, which was carried unanimously.

The CHAIRMAN briefly acknowledged the vote, and the proceedings then terminated.

Altrincham Electric Supply Company (Limited).

The second annual general meeting of the shareholders of this Company was held at the offices, Manchester, on Monday last.

The CHAIRMAN (Mr. F. B. Ross) moved the adoption of the following report:—

The result of the first year of the Company's working shows most satisfactory results, orders having already been secured for the equivalent of upwards of 10,000 8-c.p. lamps. The loss on the first year's working has been much smaller than is usually the case in similar new undertakings, in spite of the fact that the Directors have given a continuous day and night service to meet the views of many of their consumers. This has, of course, entailed considerable extra expense, but has resulted in a considerable increase in the number of consumers. He said their plant was fully employed; in fact for several months they had been compelled to have the whole of the machinery running at the same time during the hours of heavy load, and, in spite of the severe test to which the generating station had been put, they had been able to keep up a continuous and satisfactory supply of current. The Directors had considered it desirable to order a new and larger unit of plant capable of supplying current to over 4,000 8-c.p. lamps, thus doubling the capacity of the station. It was expected that this plant would be ready for use by the beginning of August. The number of consumers continued to increase satisfactorily. At present they had 118 consumers (an equivalent of 9,532 8-c.p. lamps) actually connected to the mains, and they had 21 additional consumers (an equivalent of 1,268 8-c.p. lamps) waiting to be connected, making a total of 139 consumers, with an equivalent of 10,800 8-c.p. lamps. In order to extend the area of the Company's operations, the Directors have applied for a Provisional Order for the district of Ashton-on-Mersey and that portion of the rural district of Bucklow which included Timperley. As this Order would probably be granted in July, they would be in a position to supply current to the residents in September. The Company's system of mains was divided into three portions, and they had actually laid 12⅜ miles of mains. The first year's working had resulted in a small loss, but when it was remembered that at the commencement of the year they started operations with practically no consumers connected, and that they had come on by degrees throughout the year, the number of lamps even at the end of the financial year being not nearly so great as at present, it would be seen that this result was very satisfactory. At the present time the income more than paid the expenses, so that the Directors confidently anticipate that at the end of this year's working not only would this loss be wiped off, but a profit would have been made.

Mr. W. P. J. FAWCUS seconded the adoption of the report, which was carried.

Sheffield Electric Light and Power Company (Limited).

The annual meeting of the shareholders of this Company was held on Monday at the Cutlers' Hall, Sheffield, Alderman G. Franklin presiding.

The CHAIRMAN, in moving the adoption of the report and accounts, said the net profit of the past year was £3,391. 9s. 4½d., compared with £1,943. 3s. 10½d. in 1894, and £562. 15s. 5½d. in 1893. In 1892 there were 7,734 lamps connected; in 1893, 8,419; in 1894, 15,672; and in 1895, 25,552. Last year they sold 302,965 units against 192,220 in 1894. During the year the number of customers had increased from 170 to 249, while the new customers were increasing in a satisfactory manner, and no customer who had adopted the light had abandoned it. In 1893 the cost of production and distribution was 5·14d. per unit; in 1894 it was 3·80d., and last year it was 3·55d. During the year the capital expenditure amounted to £16,426, and the total expenditure on capital account £68,614. There was a constant outlay in extensions of mains in order to meet the requirements of customers, and at the present time they had laid about twenty-five miles of pipes. After paying debenture interest and transferring certain sums to the depreciation funds, &c., a balance was available for dividend, out of which the Directors recommended the payment of a dividend of 5 per cent. Considering that the Company only got its Provisional Order three years ago, he thought this record would be considered satisfactory. The gross revenue in 1893 was £3,955; in 1894, £4,894. 9s. 4d.; and in 1895, £6,935. The Directors had deemed it advisable to make a further issue of shares, and they had offered 3,375 shares to the existing shareholders at a premium of 10s. per share. The shareholders were also invited to apply for any surplus shares; but he did not anticipate there would be many unapplied for on April 2nd, as their shares were already quoted at a premium. The Directors have purchased from the gas company a piece of land in Commercial-street for the purpose of erecting buildings for offices, &c. The Chairman next referred to some remarks made by Sir F. Mappin at the meeting of the gas company. Sir Frederick said "they should bear in mind that they had the electric light with them, that it was going to stay, and going to increase as gas had done." That was a very sensible view to take of the question, and it was what they had been telling the public for some years, and they were glad to find the gas company had at last realised the fact. Sir F. Mappin had also told them that "electricity had been with them for some years, and was quite unable to stop the increasing demand for gas." He would like to add that although gas had been with them for 80 years it was quite unable to stop the increasing demand for electric light. If he were a holder of gas stock he should not be in the least alarmed, for the gas company had plenty of scope in the two-light meters and in supplying gas to gas engines, grilling stoves, &c. The object was to supply not only the best and the brightest, but the cheapest of all illuminants; and he believed that if they could increase their day load they would be able to supply electric current at a lower price than that charged at present. Despite the fact that the bright and clear weather experienced this winter, and the absence of fogs, had given their engines very little to do in the day time, there had been an increase of 33 per cent. over the corresponding period of last year. Although the dividend they proposed to pay was not a large one, yet, considering the enormous difficulties they had had to contend with, he thought the shareholders would find the result satisfactory. The report was then unanimously adopted, and a dividend at the rate of 5 per cent. declared.

Scarborough Electric Supply Company (Limited).

The fourth ordinary general meeting of the shareholders of this Company was held last week at the Grand Hotel, Scarborough, Mr. J. Woodall, J.P., presiding. In moving the adoption of the report and accounts, the CHAIRMAN said that the statement of affairs gave them a full and concise account of the working of the Company, but he would remind them that it represented the first whole year's working, because during 1894 they had hardly settled down to work. The policy pursued by the Board had been, and would be in the future, to give as good a supply as possible to the consumers consistent with such economy as would eventually conduce to the proper working of the concern. Owing to the expense incurred by the great amount of current that was required at a late period of the autumn their receipts per lamp did not show a very large average, but the cost of production per unit would compare very favourably indeed with that of other companies which were far better situated to meet a continual demand. The result of the working for the year would allow a dividend to be paid at the rate of 2½ per cent. on the paid-up capital, after writing off sundry expenses connected with the formation of the Company. After bringing forward £418. 12s. 3d. from the revenue account of the previous year, there was a sum of £1,356. 1s. 11½d. available for distribution. They proposed that £304 should be written off from the preliminary expenses. The item of £525 for the Provisional Order would also have to be reduced regularly, and would have to be provided for in the reserve fund. In conclusion, Mr. Woodall moved the adoption of the report and accounts, and that a dividend of 2½ per cent. be declared.

Mr. A. A. CAMPBELL SWINTON (the Managing Director) seconded the motion, and gave figures showing the position of the Company, and the progress that had been made. After some discussion the motion was carried unanimously.

Anglo-Portuguese Telephone Company (Limited).

The ninth ordinary general meeting of this Company was held yesterday at the offices, 53, New Broad-street, Sir Alexander Armstrong, K.C.B., F.R.S. (Chairman), presiding.

The SECRETARY (Mr. R Rodgers) read the notice calling the meeting.

The CHAIRMAN: Gentlemen, you will see from the report that this Company continues to make very good progress in Portugal. There has been an increase in the subscribers both in Oporto and Lisbon during the year under review. The amount to the credit of profit and loss at December 31st last, after making all deductions, and including the balance brought from last year, was £8,529, from which the Directors propose to pay a dividend of 2½ per cent., and to place £3,000 to reserve, leaving £4,279 to be carried forward. We confidently hope that in the future we shall be able to augment this dividend. The report shows the income and expenditure for the year and the total number and value of our subscribers. Since the commencement of the current year the subscribers have increased, giving in Lisbon an increased income of £59 and in Oporto £136, a total increase for the first two months of this year of £136. The exceptional expenditure in Oporto during 1895 was mainly for the erection of a central exchange cupola, rendered necessary by the increasing number of wires coming into the exchange. The continuance of the high rate of exchange between the two countries is a serious matter, and but for it we should be able to pay a better dividend. Bright days, however, appear to be before the Company. I am happy to be able to add that our relations with the Portuguese Government and the municipal authorities continue to be of a very friendly character. I beg to move the adoption of the report and accounts.

This was seconded and duly carried, as was a resolution declaring the dividend of 2½ per cent.

Mr. Henry Grewing, of the London Board, and Senhor Jorge O'Neill O'Neill, of the Lisbon Board, were re-elected. Messrs. Deloitte, Dever, Griffiths and Co. were reappointed auditors, and a vote of thanks to the Chairman terminated the proceedings.

The Directors' report states that the amount to the credit of profit and loss account, including balance brought forward, is £8,529. 12s. 3d., from which it is proposed to pay a dividend of 2½ per cent., to place £3,000 to reserve, and to carry forward £4,279. 19s. 3d. During the year the Company's indebtedness in London was reduced by £1,275, and exceptional expenses had to be incurred in Oporto to the extent of about £900, and loss on exchange amounted to £2,170. The expenditure on capital account for the year amounted to £3,048. 2s. 11d. The number of paying subscribers to December 31st last was: In Lisbon 1,212, of a gross annual value of £9,237, and in Oporto 1,233 (£6,832) at total annual value of £16,069. This gives an increase in subscribers of 68, and in value of £431 over the preceding year. The continuance of the high rate of exchange between the two countries has again entailed a loss amounting to £2,170 4s. 7d., equivalent to over 4 per cent. on the share capital. This loss and the expenditure on capital account have tended most seriously to cripple the available financial resources of the Company.

Metropolitan Electric Supply Company (Limited).

The following report of the Directors of this Company for the year ended December 31st last will be presented to the ninth ordinary general meeting, to be held at Winchester House, London, E.C., on Tuesday next, the 31st inst., at 12 o'clock:—

The capital expenditure, which at the end of 1894 amounted to £628,931. 7s. 1d., has now reached a total of £675,484. 3s. This increase is caused by the development of the Company's operations, and principally consists of the cost of mains, transformers and meters for the purpose of supplying consumers. In order to meet the growing demand for current it has been found necessary to push forward with extensions both of building and plant at the Sardinia-street and Amberley-road stations, and when these extensions are fully equipped they will provide for a considerable increase of business.

A serious fire occurred at the Sardinia-street station on June 24th last, resulting in the complete destruction of the dynamo room and contents, and damage to the station generally, but, owing to the system of trunk mains and to the assistance promptly rendered by the City of London and the London Electric Supply Companies, the inconvenience to the Company's customers was reduced to a minimum. The Directors anticipate that the amounts received from the insurance companies will be sufficient to provide for the reinstatement of the buildings and plant, but as the permanent arrangements are not completed, the accounts relating to the fire cannot yet be closed, and they appear in the balance-sheet for the present as an item in suspense.

The gross revenue for the year amounted to £106,447. 8s. 9d., against £85,345. 18s. 7d. in 1894, an increase of £21,101. 10s. 2d., compared with the increase of £16,150. 14s. 3d. in 1894, which the Directors consider satisfactory. The balance to the credit of the revenue account, before providing for depreciation, is £39,154. 0s. 7d. The Directors have set aside £12,000 as an addition to the depreciation fund, carrying to the credit of the net revenue account (No. V.) the sum of £27,154. 0s. 7d., which, with the balance brought forward from last account and other receipts, makes a total of £28,961. 0s. 8d. After deducting debenture interest and other charges, there is a balance of £22,082. 4s. 4d. of which the Directors have appropriated a further sum of £1,000 in reduction of the preliminary expenses account, which is now diminished to £1,052. 10s. 4d. An interim dividend of 3s. on the Ordinary shares was paid on November 13th last, amounting to £7,485, and the Directors recommend that a further dividend of 5s. per share be now paid, making a total of 8s. per share for the year, or 4 per cent. This will absorb a further £12,475, and leave a balance of £1,122. 4s. 4d. to be carried forward.

The number of 8 c.p. lamps supplied by the Company increased during the year from 209,000 to 260,000. The present number of lamps connected is 272,000, and the applications shows no signs of decrease.

Sir John Pender, G.C.M.G., M.P., Admiral of the Fleet Lord John Hay, G.C.B., and Mr. Joseph Charles Parkinson, offer themselves for re-election as Directors, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

The report of the Company's chief engineer, dated March 16, 1896, is as follows:—

"I have pleasure in certifying that the Company's stations, machinery and plant are being maintained in an efficient condition, and have worked satisfactorily up to the present date."—FRANK BAILEY, Chief Engineer."

County of London and Brush Provincial Electric Lighting Company (Limited).

The report of the Directors for the year to December 31st last, to be presented to the shareholders at the general meeting to be held at Winchester House, Old Broad-street, E.C., at 2 p.m., on Monday, April 13th, states that the capital expended during the year on the London stations amounted to £92,151. 10s. 9d., and the investments in shares and debentures of, and the sums advanced to, associated companies to £73,396. 5s. 10d.—total of £165,647. 16s. 7d. This expenditure has been met by instalments falling due on Ordinary shares, and by the issue of 10,000 Six per Cent. Preference shares at par, which were applied for several times over. The balance to credit of revenue account amounts to £2,714. 7s. 9d., which, with £332. 5s. 10d. brought forward, makes a total of £3,046. 13s. 7d., out of which payment for the half-year to June 30th on the Six per Cent. Preference shares has been paid, and the payment of the balance for the period to December 31st last will leave £1,208. 19s. 1d. to be carried forward.

In the St. Luke and Clerkenwell Districts the cables required for the compulsory streets have been drawn in, and the transformer sub-stations have been constructed; but, owing to a strike, much delay has taken place in the completion of the generating station. Applications have been received for the equivalent of 7,000 8 c.p. lamps, of which 5,700 are now connected to the Company's mains, and the Directors anticipate that there will be a sufficient number of lamps applied for by the time the station is completed, to ensure a profit being earned from the commencement of working. The Company's operations in the Wandsworth district have been retarded owing to objections having been taken by the Local Authority to the construction of transformer boxes in the streets. All questions have now, however, been satisfactorily arranged, and the generating station on the Wandle will soon be completed. The conduits for cables have been laid throughout the district, cables are being drawn in, and it is expected that about September next a supply of current will be available.

Owing to the dissolution of the late Parliament, the St. Olave's Provisional Order was not confirmed in the last Session. It will, however, come up for confirmation in the present Session. Application has also been made by the Company for a Provisional Order for other areas in South London, and the Camberwell Vestry has consented to the granting of an Order for the district within its jurisdiction. The Company will be in a postion to supply the parishes of St. Olave, St. George the Martyr, and Camberwell from one generating station.

In reference to the provincial section of the Company's operations, the report states that during the past year the Bournemouth Company's station has been completely remodelled and enlarged, and additional plant and mains have been laid, giving a plant capacity for 27,500 8 c.p. lamps, and the equivalent of 21,000 8 c.p. lamps connected. The work of laying mains and equipping the Dover Company's station was completed last year, and an uninterrupted supply of current has been given since April, 1895. The Richmond station has yielded, with an equivalent of 5,486 8 c.p. lamps connected at December 31st last (an increase of 1,746 8 c.p. lights within the year), a profit of £230. 2s. 1d. upon the twelve months's working, against a loss of £978. 19s. 8d. in the previous year. Additional mains have lately been laid in order to reach new consumers, and further extensions are now under consideration.

Mr. A. N. Denny has resigned his seat at the Board, and the Directors have elected Mr. Emile Garcke to fill the vacancy thus created. The retiring Directors Mr. J. B. Braithwaite, junr., and Mr. A. H. Sanderson, who offer themselves for re-election, as does the auditor, Mr. R. H. Marsh.

Tramways Electrical Traction Company (Limited).

The report of the Directors of this Company, to be presented at the ordinary general meeting on Monday next, states that as the primary object of the Company was to assist the Rouen Tramways Company to electrically equip its system, contracts were entered into with the French Thomson-Houston Company and others early last year. The necessary works were immediately commenced, and sufficient progress was made to allow of some of the sections being worked electrically at the beginning of February last. The French Thomson-Houston Company has entered into an agreement to take over all the liabilities of the Company in connection with the Rouen Tramways Company, to repay the cash advances made on account of that company (with interest at 6 per cent.), and to acquire for £100,000 the 7,094 Ordinary and 48 Jouissance shares of this Company in the Rouen Company. The net result of the sale is, that there is a balance to the credit of profit and loss of £81,214. 14s. 9d., which it is proposed to appropriate as follows:—payment of interest at 6 per cent. per annum on 15,000 Preference shares (on amounts paid up, being 5s. 6d. per share) £4,125, dividend of £5 per share on 15,000 fully-paid Ordinary shares £75,000, and to carry forward the balance £2,089. 14s. 9d. The Directors propose in due course to take the necessary steps to wind up the Company.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1896, pages *318-346, &c., &c.*

ELECTRO-METALLURGICAL COMPANY (LIMITED).—This Company was registered on March 17th with a capital of £100, in £1 shares, to purchase patents, licences, secret processes, &c., regarding any invention relating to the production of chrome and other metals, and alloys of the said metals, by electrolysis or other kindred methods, and to manufacture, sell or otherwise dispose of any of the articles manufactured under any of the patents acquired by the Company.

UNITED ELECTRIC WIRE AND TELEGRAPH WORKS (LIMITED).—This Company was registered on March 18th, with a nominal capital of £6,000, in shares of £1 each, to establish, engage in, acquire and carry on the business of electricians and mechanical engineers, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, accumulation, distribution, supply and utilisation of electricity. The first subscribers, with one share each, are: G. Whitaker, W. Coleman, P. M. Dickins, electrician, E. Watson, A. M. Martin, electrician, H. Conduit, electrician, and J. Boss.

GENERAL ELECTRIC COMPANY (LIMITED).—The annual return to December 13th was filed on March 10th. The nominal capital is £85,000, divided into 7,000 First Preference, 1,000 Second Preference, 5,000 Third Preference, and 4,000 Ordinary shares, all of £5; 12,925 of these have been taken up, and 4,000 Ordinary and 1,000 Second Preference have been issued as fully paid. The full amount has been called and paid on the remainder.

GORDON ELECTRIC TRACTION SYNDICATE (LIMITED).—The annual return to December 31st has only just been filed. The whole nominal capital of £2,400, in £10 shares, has been taken up, and 60 shares have been issued as fully paid. The full amount has been called and paid on the remainder.

IMPROVED ELECTRIC GLOW LAMP SYNDICATE (LIMITED).—The statutory return to March 11th has been filed. The whole of the capital of £5.000, in £1 shares, has been taken up, and 1,318 shares have been issued as fully paid. The full amount has been called and paid on the remaining 3,682 shares. The capital was recently increased to £20,000 by the creation of 15,000 new shares of £1 each.

LYNTON AND LYNMOUTH ELECTRIC LIGHT COMPANY (LIMITED).—The annual return to December 25th has been filed. The capital is £8,000, in 1,000 Preference and 7,000 Ordinary shares of £1 each. All the Preference and 2,908 Ordinary have been taken up. £8 has been paid on 8 Ordinary shares, and the remainder have been issued as fully paid.

MADRAS ELECTRIC TRAMWAYS COMPANY (LIMITED).—The annual return to January 10th has been filed. The capital is £100,000, in £1 shares (or Rs.15). 60,669 shares have been taken up, and 7,760 issued as fully paid. The full amount has been called on the remaining 52,909, and £57,652. 17s. has been paid, including £4,743. 17s. 10d. in respect of 8,584 forfeited shares.

MAZARRON ELECTRIC LIGHT COMPANY (LIMITED).—The annual return to March 1st has been filed. The capital is £15,000, in 500 £10 Preference shares, and 10,000 £1 Ordinary shares. 151 Preference and all the Ordinary have been taken up, and 9,993 Ordinary have been issued as fully paid. The full amount has been called and paid on the remainder.

MINERS' LAMP ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to August 29, 1895, was filed on the 2nd inst. The capital is £3,000, in £5 shares, and 301 of these have been taken up; 190 have been issued as fully paid, and the full amount has been called and paid on the remainder.

MUNICIPAL ELECTRIC LIGHT AND POWER CORPORATION (LIMITED).—The annual return to January 14th has been filed. The capital is £25,000, in 2,495 £10 Ordinary, and 100 £1 Founders' shares. Thirty-seven of the former and 30 of the latter class have been taken up, and the full amount has been called.

NATIONAL ELECTRIC SUPPLY COMPANY (LIMITED)—The annual return to March 4th has been filed. The capital is £100,000, in 100 Founders' and 19,900 Ordinary shares of £5 each. All the Founders' and 10,550 of the Ordinary have been taken up, and the full amount has been called.

NORTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return to March 12th has been filed. The capital is £50 000, in 10 "A" and 49,990 "B" shares of £1 each. All the former have been taken up, but no calls have been made; 13,200 of the "B" shares have been taken up, and the full amount has been paid.

EVERED AND CO. (LIMITED).—The Directors of this Company recommend that, after payment of debenture interest, amounting to £2,416, a dividend at the rate of 7½ per cent. per annum be paid for the six months ended December 31st last, making, with an interim dividend of the same amount, 7½ per cent. for the year. The Directors also propose to pay a bonus of 1½ per cent., making a total distribution of 8¾ per cent. for the year; that £1,000 be written off plant, &c., that £1,000 be added to building fund, and that £4,809 be carried forward.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31 5/16d. per oz. (March 26th). Consols (2¾ per cent.) 109⅝—109 7/16 for money, 109¾—109¼ for account; 2½ per cent. 105½—105⅝ (March 26th). Stock Exchange Settling Days: Consols, March 30th; Stocks and Shares Continuation Day, April 13th; Ticket Day, April 14th; Pay Day, April 15th; Mining Share Carry-over Day, April 11th.

CALLS DUE.—April 27th, Rand Central Electric Works (Limited), 5s. per share.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company, after placing £6,000 to the credit of the renewal fund, have declared an interim dividend for the quarter ending March 31st current of 12s. per cent. on the Ordinary stock and 24s. per cent. on the Preferred stock (less income-tax), payable on May 1st.

BOMBAY TELEPHONE COMPANY (LIMITED).—The fourteenth annual general meeting of the shareholders of this Company was recently held at Bombay. The Chairman (the Hon. Fazulbboy Visram, C.I.E.) said the accounts for the year ended December 31, 1895, showed a credit balance of Rs.65,880-6-0, including Rs.616-11-8 from last year. The Directors proposed to pay a dividend of Re.1-4 per share (which would absorb Rs.41,968-12-0), to place Rs.6,540-6-9 to reserve, to set aside Rs.17,000 for depreciation, and to carry forward the balance of Rs.371-3-3. He said they had made satisfactory progress during the year; 86 additional lines were connected, yielding a revenue of Rs.14,525, and on December 31, 1895, there were 691 exchange and private lines at work in Bombay and Kurrachee, with a total gross revenue of Rs.123,274. The Company's exchange at Malabar Hill has been removed to Cumballa Hill, and this change would enable them to provide accommodation for a larger number of wires, and as the new exchange was more central and easier of access, they would be able to effect a saving in the construction of new lines. Mr. A. L. Paul, the parent Company's nominee, has resigned his seat on the Board, and Mr. J. B. Saunders has been elected a Director in his place. The report and accounts were then adopted.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended March 22nd were £952, against £893 in the corresponding week of 1895, an increase of £59. The total receipts for the half-year amount to £11,738, against £11,716 for the corresponding period of 1895, an increase of £22.

COTTONWOOD WATER-POWER AND ELECTRIC COMPANY (LIMITED).—Letters of allotment in connection with the recent issue of this Company have, it is stated, been posted.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY (LIMITED).—The transfer books and register of members of this Company will be closed from the 1st to the 13th April inclusive, preparatory to the payment of a dividend upon the Preference shares for the six months ended December 31, 1895.

GREAT NORTHERN TELEGRAPH COMPANY.—The ordinary general meeting of this Company will be held in Copenhagen on Saturday, April 25th, at 3 p.m., at the Exchange, when the report and accounts for the past year will be submitted.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 22nd inst. amounted to £1,149, against £943 for the corresponding week last year, an increase of £206.

MEVAGISSEY ELECTRIC LIGHT COMPANY (LIMITED).—The first meeting of this Company was held on Tuesday last. The Chairman, Mr. C. M. Grier, explained the position of the Company and the progress that had been made with the installation for street lighting. The engineer, Mr. F. H. Headley, stated that everything was in readiness for supplying electric current. On Wednesday evening last current was switched on by Mrs. Laverton.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY (LIMITED).—Subject to final audit, it has been decided by the Directors of this Company to recommend a dividend for the year ended December 31st last of 5 per cent., free of income tax.

OSWESTRY ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).—The report of the Directors of this Company for the year ended December 31st last, submitted to the annual general meeting of shareholders on the 20th inst., states that the balance of profit and loss account is £33. 6s. 1d., which it is proposed to carry forward. Up to date 24 applications for the supply of current have been received, including three contracts with the Corporation. Mains have been laid in the streets included in the compulsory area, the supply to which will be shortly completed, and the Directors are about to lay mains in Salop-road, Victoria-road, and Queen's-road. The Directors have decided to reduce, as from January 1st last, the maximum price to 6d. per unit, and all current used in any half-year beyond the amount which would be consumed during 365 hours at the highest rate of actual consumption at any moment during the half-year, will be charged for at the rate of 3½d. per unit.

POSTAL TELEGRAPH COMPANY (NEW YORK).—The Directors of this Company have declared a dividend of 1 per cent.

STOCK EXCHANGE NOTICE.—Application has been made to the Stock Exchange Committee to allow £300,000 Four per Cent. First Mortgage Debentures of the India Rubber, Gutta Percha, and Telegraph Works Company (Limited) to be quoted in the official list, in lieu of the £200,000 Four and a-Half per Cent. Debentures now quoted.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended March 20th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,694.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 933. [Vol. No. 23. XXXVI.] FRIDAY, APRIL 3, 1896. PRICE SIXPENCE.

NOTES.

THERE were present at the last meeting of the Institution of Electrical Engineers 34 members and 66 associates, and 143 students and visitors, or 243 persons in all, exactly 100 of whom were qualified to vote. The serious step—for serious step it is, unless the Institution is to be regarded as a place of light amusement—of referring back the accounts for amendment was therefore determined by a little more than a quarter of the voters actually present. The register of the Institution contains the names of 595 members and 1,583 associates, 2,178 in all; so that this vote of censure upon the Council was carried by the action of about 1·24 per cent. of the electorate. We do not suggest that this is necessarily all the active support the motion would have received had timely notice been given to *all* concerned. But we do suggest that it would be well for the Council to provide in the revised Articles of Association, which it is rumoured they have in hand, that grave decisions relative to the affairs of the Institution shall not be settled by snap divisions. Members resident in the United Kingdom, but out of London, should certainly have an opportunity of voting by post on all important questions.

To the non-telephonic member perhaps the most attractive feature in connection with the reading of Mr. DANE SINCLAIR'S instructive Paper at the Institution of Electrical Engineers last week was its excellent delivery. Notwithstanding the unfortunate delay which occurred before Mr. SINCLAIR was able to get to work, he refused to be hurried, and read his Paper with a deliberation, an emphasis and a clear enunciation which contributed not a little to lighten the usually wearisome task of listening. Mr. SINCLAIR'S Paper should bring out all the long-latent debating powers of the telephone world.

THE conversion of the energy of combustion of carbon directly into electrical energy is now being seriously attempted in many quarters, witness two articles appearing elsewhere. The latter of these is of American origin, and does not appear to us wholly convincing. The deviser of the process described therein is Dr. W. W. JACQUES, and the method used by him may be stated briefly as consisting in blowing air through a bath of fused caustic soda having a carbon anode and an iron cathode. The carbon is said to be oxidised and a current produced which is naively described as "very large," though the voltage "is low." The product of the oxidation of the carbon anode—carbon dioxide—obligingly bubbles up through the electrolyte, caustic soda to wit, the ordinary tendency of these substances to unite being apparently in abeyance under the conditions prescribed by the inventor. It is admitted, however, that the whole of the carbon dioxide cannot be trusted to remain unattached, and a notable device is adopted to correct its tendency towards combination. This consists in the addition to the electrolyte of magnesia, with which the carbon dioxide (clearly a tractable variety) unites in preference to associating itself with caustic soda. Further, the magnesium carbonate thus formed quickly decomposes, and magnesia is regenerated in a state fit for the repetition of its function. It is matter for regret that Dr. JACQUES does not describe more minutely the new modifications of caustic soda, carbon dioxide, magnesia and magnesium carbonate, which he has evidently discovered and pressed into his service.

THE other Paper, by Dr. COEHN, is of a wholly different type. It opens by a clear enunciation of the principle that a method for obtaining electrical energy directly from the oxidation of carbon may reasonably be sought, first by determining the conditions under which carbon can be attacked in an electrolyte by the aid of an external current, and then by adapting these conditions for the production of a current. How far success has been achieved by working in this direction may be gathered from the Paper itself. In friendly criticism it may be said that the precise strength and temperature of the sulphuric acid used as the electrolyte should be given, and some data afforded for calculating the efficiency of the cell. Moreover, it would be interesting to know whether any of the sensible heat applied to the electrolyte appears as electricity, in short whether any part of the current observed is of thermo-electric origin. Possibly Dr. COEHN may be disposed to enlighten us on these points.

WE commence to-day the publication of a translation of a series of articles recently contributed by M. ANDRÉ BLONDEL, the well-known arc light expert, to a French technical contemporary. In the articles which appeared in these columns last autumn M. BLONDEL treated mainly of the theoretical aspect of the problem, in the present series he deals rather with the practical side of "Public Lighting by Arc Lamps." We cannot doubt that the author's indefatigable propaganda

Digitized by Google

on behalf of the importation of more thought into our street arc lighting arrangements will in due course have its outward and visible embodiment. Generally speaking, M. BLONDEL advocates smaller carbons, dioptric diffusion and distribution of the light, and last, but not least, more elegant pillars. The gain accruing upon the use of smaller negatives was well brought out by Mr. TROTTER in the Paper he read before the Institution of Electrical Engineers in April, 1892, and it is a hard fact which will probably be generally acted upon wherever exigencies permit. The same gentleman also fathered a notable dioptric device, but to no purpose; prosaic questions of cost and cleaning have always availed to more than counterbalance the scientific advantages of proper dioptric dodges. We trust M. BLONDEL will fare better in this matter.

M. BLONDEL has a good deal to say on the "aspect fort disgracieux" of most of our home-made designs for arc-lamp pillars and lanterns. There is, it must be confessed, an excessive solidity about most English arc lamp supports; their elegance is a negligible quantity, and a factor of safety of about 1,000 has evidently been applied to them. At the same time it must be confessed that there is a certain depressing meanness about the average English street, sufficient to damp artistic effort and to render expenditure on "elegance" so much money wasted. A few of our London thoroughfares and some of our sea fronts, however, deserve better things, and we trust that whenever the electric lighting of the Thames Embankment is seriously undertaken, the design of the arc-lamp pillars will equal, if not surpass, in artistic merit the elegant and appropriate gas lamps on the parapet. The fact that the Glasgow city fathers have recently so far unbent as to ask students of the Schools of Art and Design to send in drawings for wrought-iron lamp brackets, and furthermore have actually agreed to offer "a small premium," shows to what a length the insidious cult of the beautiful has gone, and augurs well for the artistic improvement of our English arc lighting.

Two startling suggestions are put forward by Messrs. E. W. COWAN and A. STILL, in the Paper on "The Regulation of Pressure and the Reduction of Light Load Losses on Alternate Current Systems o Electric Supply," which they have recently read before the Northern Society of Electrical Engineers. One is that during periods of light loads engines and alternators should be run at one-third less than full speed, in order to reduce the losses. The other is that distribution by alternate current should be carried out, not by means of subtations nor by means of house transformers, but by placing transformers of equal size at various points along the line of distributors, the closeness of one transformer to the next being regulated by the magnitude of the load in each part. We shall be interested to see how the alternate current electrical world will receive these two proposals. In regard to the reduction of engine speed, the authors state that the experiment has been tried with hopeful results at Altrincham. Despite the upsetting of frequency and all the "constants" of the alternating transformer system, the authors recommend it. A saving in I.H.P. of 16·1 per cent. was obtained when the engine speed was dropped from 350 to 246. The loss must surely have been unusually large before, to admit of so large a saving? We are told that the effect of the alteration of frequency upon the meters is not serious, though this must depend on the kind of meter used; but the authors do not appear to consider the alternate current motor an important factor in the consideration. Arc lamps are said to stand the change-over, which is surprising considering the effect it ought to have on the coils.

Prof. FLEMING's researches on the Edison effect in glow lamps, an account of which he gave to the Physical Society last Friday, throw a great deal of light upon the apparent anomalies in the effect. But while they have added to our knowledge, they have also increased our conscious ignorance of the complex phenomena which may take place in the rarefied space between the legs of a glowing filament. Until Prof. FLEMING systematically and laboriously investigated the conditions of the Edison effect, little else was known about it than that a current would flow through a galvanometer connected to the positive leg and a middle plate in the lamp bulb, while no current would flow when the connection was between this plate and the negative leg. This apparent anomaly has now been satisfactorily explained, but in seeking the explanation Prof. FLEMING has lighted upon a host of intricate phenomena which, as Prof. SILVANUS THOMPSON pointed out in the discussion, requires to be further systematised. Evidently the few millimetres of rarefied space around a glowing lamp filament are a field rich in material for the experimenter, and promise to yield important results in regard to the conductivity of rarefied gases under various conditions of temperature and magnetic induction.

PERHAPS the most fundamental fact educed by Prof. FLEMING is that the Edison effect will only take place when the cathode is incandescent. This explains why, in ordinary circumstances no effect is observed when the negative leg is connected to the middle plate. To produce the discharge the middle plate must be made incandescent. Thus a rarefied space between a glowing and a cold electrode possesses a uni-directional conductivity. It will permit of the passage in one direction of a current from a battery of only a few volts electromotive force, while it will offer practically infinite resistance to a reverse current. The apparatus acts, in respect of an alternating potential difference, as a sieve, to sift out the currents in one direction from those in the other, and two such pieces of apparatus joined in parallel, with their heated electrodes at opposite ends, would constitute a rectifier. It may be remarked, in connection with this curiously low conductivity of rarefied gases, that Prof. J. J. THOMSON has already shown that the enormously high resistance of gases arises not so much in the bulk of the gas as immediately around the cathode. Raise the cathode to incandescence and the trouble vanishes.

STUDENTS who compare modern expositions of electromagnetic theory, such as that by OLIVER HEAVISIDE, with the older exposition by CLERK MAXWELL, doubtless notice the comparative disuse into which electromagnetic vector potential has fallen, and the growing tendency to replace it by an expression

Digitized by Google

in terms of magnetic lines of induction. Indeed, we believe that OLIVER HEAVISIDE sees no reason whatever for perpetuating vector potential, and this view is shared by many authorities. Others, doubtless schooled in a Maxwellian train of thought, prefer that the electromagnetic equations should be written in terms of it. Between the two forms of expression, magnetic induction and vector potential, there may or may not be any difference in merit, as regards mathematical treatment; but there can be little doubt that the possibility of directly measuring induction, and the impossibility of constructing an instrument to measure vector potential, constitute an enormous advantage to the former. The mention of vector potential to most electrical engineers who have once "done" theory, would conjure up visions of a bygone professorial blackboard and hard grinds at "Electricity and Magnetism," by J. C. M. There are still many youths who are laying the foundations of practical life in close study of theory, and to these the article on "The Graphic Representation of Vector Potential," by H. N. ALLEN, which we publish this week, may serve as a welcome introduction to a somewhat intricate subject.

Cable Interruptions and Repair :—

	Date of Interruption.	Date of Repair.
Aden—Zanzibar	March 16, 1896. ...	March 22, 1896.
Puerto Plata—Martinique.	December 19, 1895. ...	—
Fantarem—Manoas	March 27, 1896. ...	—

Institution of Civil Engineers—The students of this Institution will, on Wednesday next, visit the works of the Waterloo and City Railway, assembling at 2:30 p.m. at 15 Upper Ground-street, Blackfriars.

The Telegraph Revenue.—The receipts from the telegraph service for the financial year ending March 31, 1896, amounted to £2,840,000, against £2,580,000 for the year ending March 31, 1895, an increase of £260,000, or 10 per cent.

University College, Bristol.—Courses on civil engineering, mining engineering and electrical engineering will be held at this college during the third term, commencing on April 21st. Lectures will also be delivered on electrical technology.

Prof. Perry.—Prof. Perry has been appointed to the chair of Mechanics and Mathematics at the Royal College of Science. An enthusiastic worker at Finsbury Technical College since 1882, Prof. Perry will carry to South Kensington not only the best wishes of his colleagues and students at Leonard-street, but also their regrets. The City's loss is Kensington's gain.

Royal Institution.—The following are some further particulars with regard to the Friday evening meetings after Easter: April 17th, M. G. Lippmann, Membre de l'Institut (France), "Colour Photography;" May 8th, Prof. Silvanus P. Thompson, D.Sc., F.R.S., "Electric Shadows and Luminescence;" May 22nd, Prof. J. A. Ewing, F.R.S., "Hysteresis;" June 5th, Prof. J. A. Fleming, D.Sc., F.R.S., "Electric and Magnetic Research at Low Temperatures."

Expiring Patents.—On Sunday next, the 5th inst., will expire patent No. 1,642 of 1882, granted to W. H. Akester for "IMPROVEMENTS IN INCANDESCENT ELECTRIC LAMPS." The Akester lamp was well known in the early days of incandescent lamp manufacture.——On Sunday next will also expire patent No. 1,647 of 1882, granted to St. George Lane-Fox for "IMPROVEMENTS IN THE MANUFACTURE OF INCANDESCENT ELECTRIC LAMPS." The claim advanced is for "producing by means of an electric arc . . . the necessary heat to cause a deposit of carbon upon the ends of carbon filaments for incandescent electric lamps when immersed in a medium of coal gas or other carbon compound."

Fire Office Rules.—The Liverpool, London, and Globe Insurance Company have issued a new set of rules for electric light and power installations, covering pressures not exceeding 250 volts. The continuous insulation of the cable is not to be less than 300 megohms per mile when tested in water at 60°F. after one minute's electrification. And the complete installation must be "so insulated from earth that the total leakage to earth does not exceed $\frac{1}{20000}$th of the maximum current used, when tested at double the working voltage, or at 200 volts." This Insurance Company have also issued a large sheet for hanging in dynamo rooms, containing suggestions for insuring safety.

Heavy Claims against Tramway Companies in America.—The New York City authorities have filed claims against tramway companies aggregating about £130,000. By the terms of their franchises the tramways are required to pave between their tracks and for two feet on either side, and to keep this pavement in constant repair. The claims sent to the Law Department represent work done by the city in paving and repairing. There are 50 claims, and 20 tramway companies are involved. The companies claim that they were willing to keep the old pavement repaired, but that they were under no obligation to put down a new pavement every time the city determined to repair a street.

Cast Iron Pipes.—A correspondent has pointed out to us that the quotations for cast iron spigot-and-socket pipes, which were made in the article on "Cast Iron and Stoneware Conduits," in our issue of the 13th ult., are considerably above the average ruling prices. On comparing the quotations given with the price actually paid by an electric supply concern, we find that this is the case. The quotations, which were taken from various price books, should be subjected to a discount of at least 25 per cent., the actual cost varying both with the quantity of pipe concerned and with local considerations. The engineer of an electric supply concern in the north of England recently informed us that he pays 1s. 6d. per yard for 2in. cast iron pipe delivered.

Electric Heating.—Mr. H. J. Dowsing has resigned his appointment as manager of the electrical heating and cooking department of Messrs. Crompton and Co. (Limited), and has taken offices at 14, Budge-row, Cannon-street, E.C., where he will carry on the business of electric heating, adding several other special departments in the application of electricity. Mr. Dowsing has been nearly 15 years connected with Crompton and Co., first on the outdoor staff, then as London office manager, and finally manager of the heating department which he established, the patents covering the processes bearing his name in conjunction with that of Mr. Crompton. Mr. Dowsing will place his experience at the disposal of those thinking of adopting electric heating.

Personal.—Mr. W. B. Sayers has resigned his position as works manager to Messrs. Mavor and Coulson, a post which he has held for the past 5½ years. Mr. Sayers, who has had some 16 years' experience in the design, construction and installation of machinery and apparatus for electric lighting and electric transmission of power, &c., now proposes to start business as a consulting engineer and electrician at 189, St. Vincent-street, Glasgow. Mr. Sayers' name is perhaps best known in connection with an ingenious and useful device for the prevention and control of sparking, and the production of continuous-current dynamos without winding on the field magnets and constant-pressure dynamos without series winding, a device which a leading authority on dynamo design described, at the time his Paper was read before the Institution of Electrical Engineers, as "the greatest advance that had been made in the design of direct-current dynamos during the past 10 years."

South Shields.—Mr. J. A. Jeckell, the electrical engineer to the borough of South Shields, following the example set by some of his *confrères*, has published a pamphlet setting forth the advantages of the electric light and the terms upon which it is to be obtained at South Shields. As we have stated, this has been done before in other places; and we understand that engineers who have tried the plan say they have reason to believe in its success. The great thing to aim at in a pamphlet of this kind is lucidity; for the plain man is apt to be frightened if he meets an intricate array of scientific phraseology. No doubt "the greater or lesser brilliancy of the light from gas, oil or candles depends upon the greater or lesser

Digitized by Google

amount of oxygen (which is the one ingredient in the atmosphere necessary to sustain human life) which they abstract from the air"; but a tradesman would probably seize the point quicker if just told that gas makes the air unhealthy while electric light cannot.

The Lyons Power Transmission Scheme.—The Société Lyonnaise des Forces Motrices du Rhône, which proposes to utilise part of the water-power of the Rhone for the generation of electricity for light and power, has awarded the contracts for part of the plant. The complete plant is expected to produce 20,000 H.P., and will consist of 16 turbines of 1,250 H.P. each. The available fall varies from 30ft. to 40ft. The turbines have vertical shafts and are of the reaction type, working with a suction tube, and the generators are connected direct to the vertical turbine shaft. By a special arrangement the large turbines can be made to run at 120 revolutions, while the turbines driving the exciter dynamos run at 250 revolutions. The generators are each to have an output of 1,250 H.P. To start with, 8 turbines of 1,250 H.P. each, with generators, and the necessary exciter dynamos with their turbines, will be erected, the dynamos being made by Brown, Boveri and Co., of Baden, the turbines by the well-known Swiss firm of Escher, Wyss and Co., of Zurich.

Röntgen Rays at the Académie des Sciences.—The *Comptes Rendus* for March contains no less than twelve communications relating to X-rays. M. A. LAFAY describes the following experiment: Underneath a Crookes tube, about ½cm. from the most brilliant portion, he arranged a leaden screen pierced by a slit 2mm. wide. Some 4cm. lower he placed a second lead screen pierced by a 5mm. slit, completely closed by a very thin strip of silver foil supporting a platinum wire 1·5mm. in diameter, exactly in the axis of the slit. The silver foil was connected to the negative pole of the induction coil. The rays then passed between the poles of an electro-magnet capable of generating a field of 400 C.G.S. units, the lines being parallel to the slit. In a first experiment M. Lafay with a sensitive plate, 8cm. away from the poles of the electro-magnet, obtained no certain trace of deflection. With the plate 15cm. off, however, there were unmistakable evidences of deflection of the ray in the same direction as would be the case with cathode rays.

Lord Kelvin's Jubilee.—Lord Kelvin will, in the autumn of this year, complete the fiftieth year of his tenure of the Chair of Natural Philosophy in the University of Glasgow. The prospective jubilee is regarded with great interest in the University and City of Glasgow. It has been thought fitting that the occasion should receive a wide recognition, and a joint Committee, including representatives of the University and the Municipality, are taking measures to secure the participation of Universities, and scientific and learned bodies, both in the United Kingdom and abroad. These bodies are now being invited to send representatives to the celebration to be held in Glasgow on June 15th and 16th, on the former of which days a *conversazione* will be held in the University, and on the latter a dinner in the City Chambers, the arrangements comprising, among other items germane to the occasion, an exhibition of mechanical, electrical, and scientific apparatus, illustrating Lord Kelvin's inventive and constructive genius. Invitations will also be issued to others besides representatives of the bodies mentioned, including men of note in academic and professional circles, and in the arts and industries to which Lord Kelvin's life-work has been most directly related, as well as prominent citizens of Glasgow and others connected with the University by official and other ties. It is believed that there will be a cordial response to the invitations, and that in June next a distinguished company will be brought together to do honour to Lord Kelvin on the occasion of the jubilee of his Professorship in Glasgow University.

Influence of Röntgen Rays on the Conductivity of Dielectrics.—At a recent meeting of the Cambridge Philosophical Society, a Paper on "The Leakage of Electricity through Dielectrics traversed by Röntgen Rays" was read by Prof. J. J. Thomson and Mr. J. A. McClelland. This Paper, says *Nature*, contains an account of a series of experiments made with the object of investigating the laws regulating the passage of electricity through dielectrics transmitting Röntgen rays. This phenomenon has been discussed by one of the authors in a Paper read before the Philosophical Society on January 27th, and also in one read before the Royal Society on February 13th. The first experiments relate to the rate of leak through different gases under similar conditions as to pressure and potential gradient. The gases used were hydrogen, ammonia, carbonic acid, air, coal gas, sulphuretted hydrogen, chloroform, chlorine, bromine, iodine, sulphur chloride and mercury vapour. Numbers showing the rate of leakage in these gases relatively to that in air are given. In general, though the rule is not without exceptions, the greater the molecular weight of the gas the more rapid the leakage. In hydrogen the leak was slowest, and in mercury vapour fastest; the rate in the vapour of boiling mercury was about 28 times as fast as hydrogen. The rapid rate in mercury vapour is interesting, for this gas offers great opposition to the passage of an ordinary electric discharge. The rate of leak in the halogens is also very rapid, and a tube containing a charged plate in chlorine gas is a very sensitive and convenient method of measuring the intensity of these rays. The rates of leakage in air at different pressures were investigated; it was found that the rate of leak was lower at a low pressure than at a high one, and was over a considerable range of pressure approximately proportional to the square root of the pressure. The effect of temperature was also investigated, and it was found that through air the rate of leak was lower at a very high temperature than at the temperature of the room, but there was an intermediate temperature at which the rate was a maximum. The most remarkable thing about this leakage under the influence of these rays is that the rate is almost independent of the potential difference. Thus when the high potential plate was 5 volts above that of the low, the rate of leak was appreciably greater than when the potential difference was 1 volt, but the rate was no greater when the potential difference was 500 volts than when it was 5. A series of experiments were made to find how the rate of leakage varied with the distance from the bulb; the bulb was placed behind a metal plate with a hole in it; it was found that in the neighbourhood of the phosphorescent glass the reciprocal of the rate of leakage was a linear function of the distance from the phosphorescent patch, but at a greater distance it diminished more rapidly than is indicated by this law. The measurements are not inconsistent with the view that the rate varies inversely as the square of the distance from a place in the neighbourhood of the *negative electrode*. Some experiments on the rate of leakage produced by the rays after passing through a varying number of strips of tinfoil seem to indicate that these rays are not all of one kind.

Contemporary Electrical Science.—The management of electric waves is making rapid progress. Herr VON LANG, in *Wiedemann's Annalen*, describes Quincke's familiar apparatus for showing the interference of sound waves passing through two branches of a tube of unequal length, except that electric waves are substituted for sound waves. As the length of one of the branches is varied, distinct maxima and minima are shown by the "coherer" employed for their detection. Filling one of the branches with another dielectric, such as paraffin or sulphur, enables the observer to determine the velocity of the waves in those substances, and hence their refractive indices. They come out rather higher than usual.——L. ZEHNDER gives one more rule for the directions and signs of the various occurrences in the electromagnetic field. It is perfectly general and very simple in form, but its application seems to require profound study.——JOSEPH VON GEITLER examines the wave systems given out by the more complicated forms of Hertz generators. He finds that for every length of the secondary circuit the primary circuit emits several wave systems of different thicknesses and intensities. He determines these intensities by means of resonators.——W. HOLTZ recalls that in 1880 he found that conductors were more opaque to the electric glow discharge than dielectrics. This result was at the time so "absurd" that he began to doubt it himself. It has now been made very probably by Röntgen's discoveries. Herr Holtz calls upon physicists to make further experiments in this direction, being himself prevented by illness from doing so.——About certain other Papers of great interest we shall have something more to say.

THE ZUFIKON-BREMGARTEN WATER POWER TRANSMISSION PLANT.

To *l'Industrie Électrique*, of February 10th, Mr. P. Gasnier contributed a detailed description of an interesting plant for the electric transmission of water power from Zufikon, in the Bremgarten district of Canton Aargau, Switzerland, to Wohlen in one direction, and to Zurich in the opposite direction. The turbine house is conveniently situated on the river Reuss, at a place where the declivity of the stream is great, and where the sharp curvature of the course enables a considerable length of stream to be included in the available fall. The fall is improved by a weir, which has raised the head from 5·0 metres (16·4ft.) to 5·65 metres (about 18·5ft.). The bend of the river, extending some 1,300 metres (4,264ft.) along the stream on a 3·8 per cent. declivity, is artificially bridged across by a straight tunnel 350 metres (1,148ft.) in length, the upper end of which terminates in a short canal or penstock and sluice weir just above the main river weir. The plan of this mill-site is shown in Fig. 1. At the lower end of the fall the outlet from the turbine house is protected from being choked by the rush of the by-water by means of a curved discontinuous weir, as shown in Fig. 1. The tunnel and, indeed, the entire plant, has been constructed to take a maximum flow of 25 cubic metres (883 cubic ft. = 5,500 gallons) per second, but it is anticipated that in summer the flow will not exceed 15 cubic metres (3,300 gallons) per second. With the maximum flow of 25 cubic metres, the loss of head in the tunnel is 0·32 metres (1·05ft.) leaving a head available at the turbines of 5·33 metres (17·45ft.). With the lesser flow the loss of head would, of course, be less, and the available head greater. The tunnel is constructed with a regular declivity of 1·2 per cent., and with a sectional area of 13·62 sq. metres (146·6 sq. ft.). It is cemented throughout. The velocity of flow through the tunnel is 1·85 metres (6·17ft.) per second.

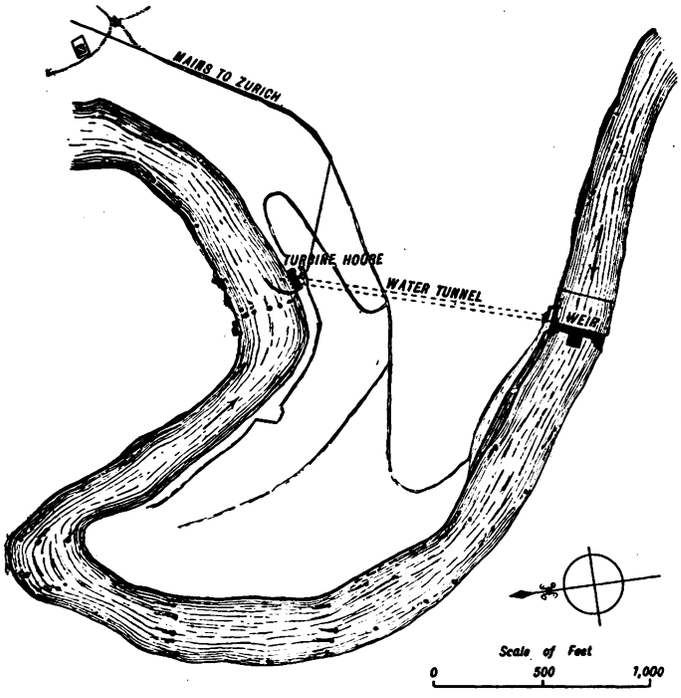

FIG. 1.—Zufikon-Bremgarten Installation. Plan of Mill Site.
Mains. Roads.

The turbine house is equipped with plant for a total of 1,300 H.P., usefully developed. There are four pairs of vertical turbines, each pair capable of developing 325 H.P. at 115 revolutions per minute. These engines were built by Messrs. Escher Wyss & Cie., whose works at Zürich are among the establishments supplied with power. Fig. 2 shows a vertical section through the power house. It will be seen that each pair of turbines is mounted on the same vertical shaft, which is carried up through the roof of the wheel pit. The admission of the water to the upper machine is downwards, and to the lower machines upwards, a balance of the reaction thrusts being obtained by this arrangement. It should be explained that beyond this equalisation of the reactions, equilibrium is further assisted by means of a plain disc on the lower engine, the upward pressure of the water on this disc serving to support the weight of the moving parts, including the dynamo. Thus the load on the footstep bearing is reduced to a minimum. The turbines are of the parallel-flow "drowned" type, and are assisted by a suction tube built into the masonry of the wheel pit.

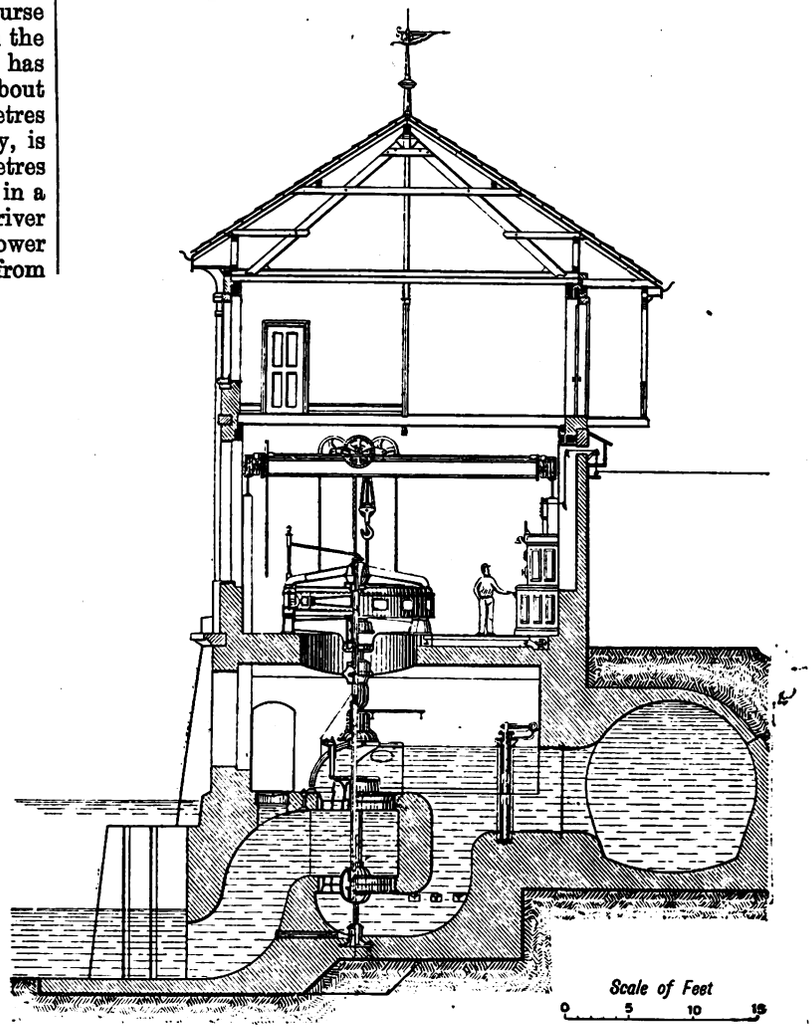

FIG. 2.—Zufikon-Bremgarten Installation. Vertical Section of Generating Station.

Built into the roof of the wheel pit, which also forms the floor of the dynamo room, are the frames of the four electric generators. These machines are constructed to develop three-phase current at 5,000 volts, the normal output from each machine being 224 kilowatts. They were built at the Oerlikon works, and have fixed armature coils, within the pitch circle of each of which rotates an inductor consisting of 52 magnet poles. There are 78 bobbins on each armature, the induced frequency being 50 per second. Each complete machine has a diameter of 3·60 metres (11·8ft), and weighs 20,000 kilogrammes (19·68 tons), the moving parts of the machine having an extreme diameter 2·984 metres (9·77ft.), and weighing 12,000 kilogrammes (11·81 tons). The four generators are excited by either of two 11 kilowatt continuous-current machines, the running machine also serving to light the buildings. The exciters are of the 4-pole Oerlikon type, and develop 130 volts at a speed of 600 revolutions per minute. They are driven by a separate little turbine of 34 H.P. by means of bevel gear and friction clutches.

The electric power thus generated is distributed as follows: The greater part is transmitted over 20 kilometres (12·5 miles) to the environs and town of Zurich, where 400 H.P. is taken

Digitized by Google

by the works of Escher Wyss et Cie, and 250 H.P. by another large works; the remainder of the power, some 80 H.P. is transmitted a distance of 7 kilometres (4½ miles) to Wohlen, for electric light and power supply. Overhead lines are used throughout, a duplicate line of two sets of three wires being erected between the station and Zurich. A single three-wire line conveys the power to Wohlen. The wires on the Zurich lines are of 7·7mm. diameter, and on the Wohlen lines 4mm. Oil insulators are used throughout all the circuits. Crossing a railway *en route* to Zurich the lines are carried through a protecting staging, supported by light steel girders 16·5m. (54ft.) apart. The ordinary poles are 148ft. apart.

A total efficiency of 77 per cent. has been obtained on this installation. This is composed of the following items:—Efficiency of generators comprising excitation, 94 per cent.; efficiency of the Zurich lines, 85 per cent.; efficiency of transformers, 97 per cent.

THE GRAPHIC REPRESENTATION OF VECTOR POTENTIAL.

BY H. N. ALLEN (University of Nebraska).

The object of the present Paper is to show how the distribution of electromagnetic vector potential can in certain cases be represented graphically. The electromagnetic vector potential is a quantity having a fixed magnitude and direction at every point of the field, such that if any closed curve be taken in the field, and if the product of the tangential component of the vector potential into the length of the element

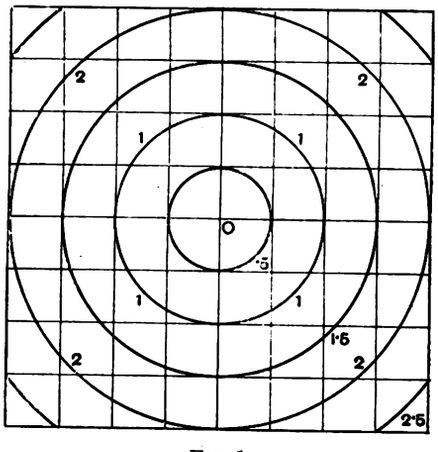

FIG. 1.

of the curve be integrated right round, the result will be equal to the electromagnetic induction through the surface bounded by the curve. The simplest example is that of a uniform field. Any line parallel to the field may be taken as having zero vector potential, and a series of cylinders, with this line as axis, will be surfaces of equal vector potential.

In Fig. 1 is represented a section at right angles to a field of unit intensity, the sectional area of each tube of induction being 1 sq. cm. The field is directed upward. Then along the circumference of a circle drawn with the point of zero vector potential as centre, and with radius r, the vector potential is $\frac{1}{2}r$, is tangent at each point to the circumference, and is in the counter-clockwise direction. For under these circumstances the integration round the curve is obtained by multiplying the constant value of the vector potential by the length of the curve. This gives $\frac{1}{2}r \times 2\pi r = \pi r^2$. This is also equal to the area of the circle, and so, since the induction is unity, to the induction through the surface.

In general the vector potential at a distance r from the origin is $\frac{1}{2}Br$, where B is the induction. In the case of infinitely long straight parallel wires the surfaces of equal vector potential coincide with the surfaces bounding the tubes of induction. The direction of the vector potential is parallel to the wires.

In Fig. 2, for example, the induction tubes due to two equal parallel currents in opposite directions are represented. Let the current on the right be directed upward at right angles to the plane of the paper. The positive direction of the vector potential will be the same. The line o C being taken as having zero vector potential, the lines on the right will have the values 1, 2, 3, &c., in order, and those on the left negative values, indicating an opposite direction.

At the two points, D and E erect perpendiculars to the plane of the paper 1cm. long, and join the extremities to form a rectangle. The induction through the surface is seen to be 5.

The vector potential at E is 3, and the integration outwards along the centimetre long side of the rectangle gives also 3. The integration from E′ to D′* parallel to the plane of the paper gives zero, since there is no component in this direction.

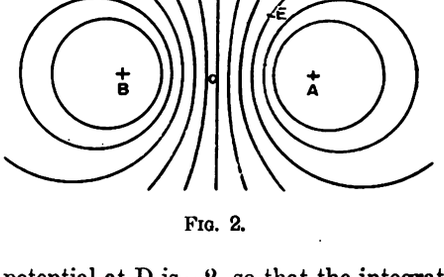

FIG. 2.

The vector potential at D is −2, so that the integration in the negative direction from D′ to D gives the value + 2. The component along D E is zero. The total integration round the boundary is then 5, the same as the induction through the surface.

In this connection Fig. 3 may be of interest. It shows the induction tubes and surfaces of equal vector potential both within and without two parallel cylindrical conductors conveying equal currents in opposite directions. Only half of one of the wires is shown, its section being indicated by the line O B A. In general the surfaces of equal vector potential do not coincide with the surfaces bounding the induction tubes. They can, however, be drawn easily when the latter can be constructed.

In Fig. 4, for example, I., II., III., IV. are lines of force, such that, when the figure is rotated about the horizontal line,

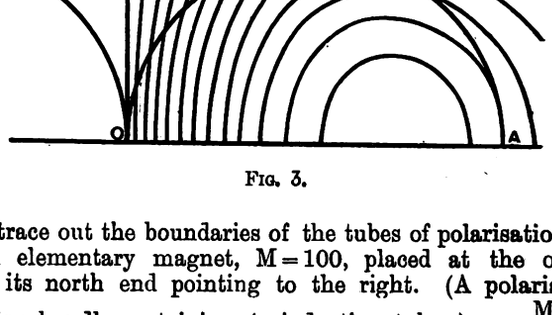

FIG. 3.

they trace out the boundaries of the tubes of polarisation due to an elementary magnet, M = 100, placed at the origin, with its north end pointing to the right. (A polarisation tube is a bundle containing 4π induction tubes.) $r = \frac{M \sin^2\theta}{2n}$ is the equation of the nth line of force.

Take a point on the line of force I., the perpendicular distance of which from the axis of symmetry is 2cm. The vector potential at this point will be unity, directed perpendicularly upward from the plane of the paper. The vector potential will have the same value at a point on the line II. distant 4cm. from the axis, at a point on III. distant 6cm., and at a point on IV. distant 8cm. If n be the number of the lines of force, and y the perpendicular distance of a point

* Points perpendicularly above E and D, at right angles to the plane of the paper.—ED. *E.*

Digitized by Google

on it from the axis, this point, when the figure is rotated about the axis of the magnet, will trace out a circle through which pass n polarisation tubes, or $4\pi n$ tubes of induction.

The vector potential is always tangential to this circle, and has a constant value A for all points on it. The length of the circumference being $2\pi y$, the integration round the curve will give $2\pi y$ A. Since this is equal to the induction $4\pi n$, it follows that A equals $\frac{2n}{y}$. If, then, we seek on the line of force n a point the ordinate of which is equal to $\frac{2n}{A}$, we obtain a point where the vector potential is A, and continuing this for the other lines of force we obtain a series of points through

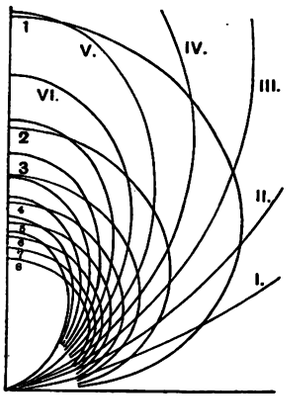

FIG. 4.

which a curve of equal vector potential, like the curves 1, 2, 3, 4 in Fig. 4, can be drawn. In this figure it can be shown that the equation of the vector potential surface A is $r = \sqrt{\frac{M \sin \theta}{A}}$. The form is the same in this case as that of the surfaces of equal scalar potential, though the axis of symmetry of these latter is at right angles to that of the vector potential surfaces.

The method described is applicable to all cases in which the lines of force can be drawn by Maxwell's method. It is hoped that it may help some to form a more tangible conception of this important quantity.

THEORY AND CALCULATIONS OF ASYNCHRONOUS ALTERNATE CURRENT MOTORS.

BY A. HEYLAND (BUDAPEST).

(*Continued from page 653*).

PART II.—MONOPHASE MOTORS.

The novelty of this simple theory of monophase motors to be developed as follows, is that *all the conclusions arrived at with regard to polyphase motors can also be applied to monophase motors.* The different conditions with which we shall have to deal can essentially be met by introducing an *apparent stray coefficient* (leakage factor) instead of the stray coefficient as previously defined

No Load.

For the present we will assume that there is perfect synchronism between the periods of the primary alternating current and the short-circuit armature.

The monophase inducing armature would in itself produce a simple alternating field, whose sense would be determined by the coils on the primary armature. This field would, however, not appear as such in the short-circuit armature turning in synchronism, since this armature passes through 180deg. during one alternation; an *intermittent field* of constant direction would result. This intermittent field would, in its turn, induce current in the coils which by their magnetising effect would counteract the pulsations of the field, so that we have in reality to deal with a field of *mean intensity*, and not with one varying between zero and a maximum. The less the resistance of the short-circuit coils, the more this opposing tendency will document itself. Where the intermittent field would exceed the mean strength, the induced currents will weaken the magnetisation; in the opposite case they will strengthen the field.

Figs. 1 to 4 illustrate the four characteristic positions of one period, as viewed from the fixed inducing armature. The

FIG. 1.

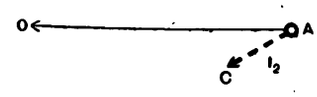

FIG. 1A.

phases of the primary currents and the positions of the short-circuit armature are indicated. In positions Figs. 2 and 4, the induced currents I_2 of the short-circuited armature flow contrary to both the primary current I_1 and to the field; the magnetising current is hence represented by the difference $I_1 - I_2 = I$. In Figs. 3 and 1, I_2 follows the sense of the field, and is the magnetising current.

For coils of small resistance the armature field will be constant. Under this supposition the rotary field can be resolved into two components at right angles to each other, the one

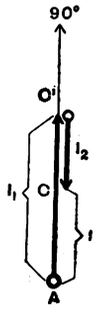

FIG. 2.

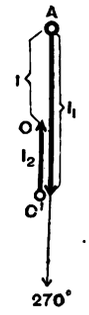

FIG. 4.

which we will call the first being $I = I_1 - I_2$ (Figs. 2 and 4), the second I_2 (Figs. 3 and 1). We will assume the magnetising effects of those two components as equal to one another. The first component, combined with the stray field, must call forth in the inducing coils an E.M.F. which corresponds to the tension K at the terminals. The second component has no influence upon the primary circuit. It only serves to produce a rotating field, by which means the primary phase component, our first component, is enabled to act as if there were a second primary phase at right angles to the first, such as exists in the

FIG. 3.

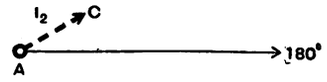

FIG. 3A.

diphase motor. If we have a synchronous diphase motor, and suddenly cut out the primary phase II., primary phase I. will continue to function, and will replace the magnetising current of the missing primary phase II. by inducing in the short-circuit armature the first-mentioned component II.

The induction currents I_2 will claim a certain expenditure of energy. Theoretically, therefore, *i.e.*, apart from losses by friction, perfect synchronism will not be attained at no load in the case

Digitized by Google

of the monophase motor, whilst it was attained in the case of the polyphase motor. The energy absorbed by l_2 is, however, insignificant in comparison with the losses by friction; we may, therefore, state that theoretically the conditions of no load coincide with those of synchronism.

There is an essential difference between the monophase and the diphase motors, though. The current at no load, which for polyphase connections also represents the magnetising current I_1 of phase I., here rises to $I_1 = A C^1$ (Fig. 2) which is the sum of the magnetising current I. of phase I. and of I_2 magnetising current of phase II.

Indirectly I_1 becomes the magnetising current of both phases; we will therefore term it the *apparent magnetising current* of monophase motors, I^I, whilst I^M would be the actual magnetising current of polyphase motors.

With regard to I^I, we know that at positions I. and II. the armature field remains constant; in position I. the main field together with the primary stray field would be the same as with diphase connections.

If H_2 is the armature field, H_1 the primary field (main field plus primary stray field), c a constant dependent upon iron dimensions and number of coils, then in position I. (Figs. 2 and 4) $H_2 = c(i - \tau_2 i_2)$;

position II. (Figs. 3 and 1) $H_2 = c(i_2 + \tau_2 i_2)$,

and therefore, H_2 being constant, $I = I_2(I + 2\tau_2)$.

Further, $H_1 = c(i + \tau i^I)$

and $i^I = i + i_2$,

hence $H_1 = c\, i^I \dfrac{1 + 2\tau_1 + 2\tau_2}{2 + 2\tau_2}$.

As regards i^M, we know that for diphase connections

$$H_1 = c\, i^M (1 + \tau_1),$$

therefore $$\frac{i^I}{i^M} = \frac{1 + 2\tau_1 + 2\tau_2}{2 + 2\tau_1 + 2\tau_2};$$

now $$\tau = \frac{\tau_1 + \tau_2}{2},$$

$$\frac{i^I}{i^M} = \frac{1 + 4\tau}{2 + 4\tau} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

We recognise that i^I is approximately equal $2 i^M$. So far only one difference has arisen between monophase and polyphase motors; the i^M of the latter has to be replaced by a greater i^I in the case of the former. The other relations deduced for polyphase motors should also hold, provided we further substitute, as remarked above, an *apparent stray coefficient* τ^I for the stray coefficient τ, as previously defined.

We had derived

$$\tau_1 = \frac{\frac{h_1}{i_1}}{\frac{H}{i^M}} \qquad \tau_2 = \frac{\frac{h_2}{i_2}}{\frac{H}{i^M}} \qquad \tau = \frac{\tau_1 + \tau_2}{2}.$$

Analogously

$$\tau_1{}^I = \frac{\frac{h_1}{i_1}}{\frac{H}{i^I}} \qquad \tau_2{}^I = \frac{\frac{h_2}{i_2}}{\frac{H}{i^I}} \qquad \tau^I = \frac{\tau_1{}^I + \tau_2{}^I}{2}.$$

As $\frac{h_1}{i_1}$, $\frac{h_2}{i_2}$ and H have undergone no change, we find

$$\tau^I = \tau \frac{i^I}{i^M} = \frac{2\tau}{1 + 4\tau} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Motor Under Load.

The motor under load lags behind synchronism by a slip, S. We at once recognise a striking difference in the behaviour of the monophase motors. In their case, the component II. of the rotating field is carried round by the armature, as is indicated in Figs. 1A and 3A, and will hence show the same slip, S. There is, therefore, no phase difference between the armature and the component II. The explanation is that the latter component does not do any work; it simply magnetises. The slip between the armature and the component I., on the contrary, is doubled; the motor works as if the slip were 2 S, and not S.* For the further study of this peculiarity, it will be found profitable to introduce an *apparent short-circuit resistance* $W_2{}^I$. Electrically the conditions of a polyphase motor remain unchanged, as we have seen, so long as the ratio $\frac{\text{slip S}}{\text{short-circuit resistance } W_2}$ is not affected. For the monophase motor, we have to substitute $\frac{S}{W_2{}^I} = \frac{2S}{W_2}$; hence

$$W_2{}^I = \frac{W_2}{2}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

The lag of the component II. finally diminishes the torque of the monophase motor. When the field of phase II. lags behind by an angle of S × 90deg., the (1 − S)th part only of the live primary turns can exercise any attraction upon the field of the armature. The pull of the motor is hence diminished by the factor (1 − S) per phase, as compared with that of an equivalent diphase motor; that is to say, if the torque of a diphase motor is Z′ per phase, its total pull therefore 2 Z′, and the pull of the monophase motor is Z^I, then

$$Z^I = Z'(1 - S). \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

The work L done per phase is given by the product torque × angular velocity. The torque curve of a monophase motor will, therefore, be identical with the power curve of an equivalent diphase motor.

$$Z^I = \frac{\frac{W_1}{W_2{}^I} S}{1 + \frac{2}{f^I}\frac{W_1}{W_2{}^I} S + \frac{1 - f^I}{(1 + f^I)\epsilon_1{}^2 f^I{}^2}\frac{W_1{}^2}{W_2{}^I{}^2} S^2} (1 - S)$$

$$= \frac{a^I S}{1 + b^I S + c^I S^2}(1 - S). \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4a)$$

The results may be summarised as follows:—

The characteristic of a monophase motor is identical with the characteristic of a polyphase motor with approximately *twice the magnetising current, twice the stray coefficient, and half the short-circuit resistance.*

The "approximately twice" is represented by $\frac{2 + 4\tau}{1 + 4\tau}$.

The torque curve of the monophase motor is identical with the power curve of the polyphase motor.

The apparent magnetising current is $I^I = i^M \frac{2 + 4\tau}{1 + 4\tau}$, (1)

the apparent stray coefficient is $\tau^I = \frac{2\tau}{1 + 4\tau}$, . (2)

the apparent short-circuit resistance $W_2{}^I = \frac{W_2}{2}$, . . (3)

the torque of the monophase motor $Z^I = Z'(1 - S)$. (4)

COMPARISON BETWEEN MONO- AND POLYPHASE MOTORS.

Characteristics.

We are now in a position to proceed to a comparison between motors of the two types. We will take two extreme cases—(*a*) slight straying (magnetic leakage), $\tau = 0{\cdot}0131$; (*b*) considerable straying, $\tau = 0{\cdot}0625$; and we will inquire into the changes consequent upon the variations in these coefficients.

Example (*a*) $\tau = 0{\cdot}0131$ is illustrated in Fig. 5A. The larger outer circle C C″ is the characteristic of the polyphase motor, the inner circle $C^I C^{I\prime\prime}$ that of the monophase motor of the same construction. Fig. 5B depicts case (*b*) in the same manner.

The apparent magnetising current is ..... $i^I = A C^I$.
,, actual ,, ,, of phase I.... $i = A C$.
,, ,, ,, ,, of phase II... $i_2 = C^I C$.

The characteristic of the polyphase motor is based upon the actual magnetising current i^M and τ, as $\frac{A C}{O C_c} = 4\tau$. The characteristic of the monophase motor is based upon the apparent magnetising current $i^I = i^M \frac{2 + 4\tau}{1 + 4\tau}$, and the apparent stray

* Cahen, *Elektrotechnische Zeitschrift*, 1895, No. 30, has come to the same conclusion in a different way.

Digitized by Google

coefficient $\tau^I = \frac{2\tau}{1+4\tau}$, as $\frac{A\,C^I}{C^I O_c^I} = 4\tau^I$. The $i_2 = C^I C, C^{I'} C, C^{I''} C$ exceed the corresponding quantities of the polyphase motor by the wattless component $C^I C$. D, which approximately denotes the position of rest, is common to both circles, and signifies that at rest the two motors do not differ electrically; this must, of course, be so.

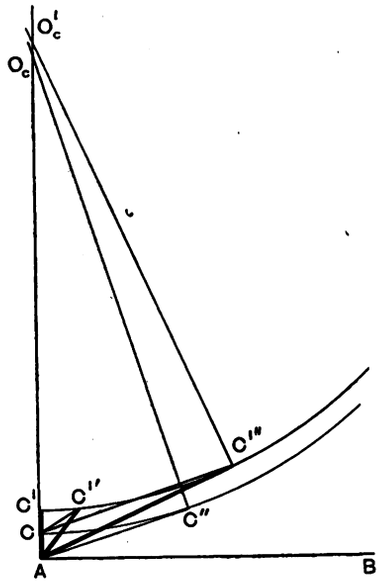

FIG. 5A.

The maximum power factor f^I can be deduced, as has been explained with regard to polyphase motors. For the latter, f would, in case (a), be:—$f = \frac{1}{1+4\tau} = 0{\cdot}95$; for the monophase motor we have $f^I = \frac{1}{1+4\tau^I} = \frac{1}{3-2f} = 0{\cdot}91$. In case ($b$) we find $f = 0{\cdot}80$, $f^I = 0{\cdot}715$.

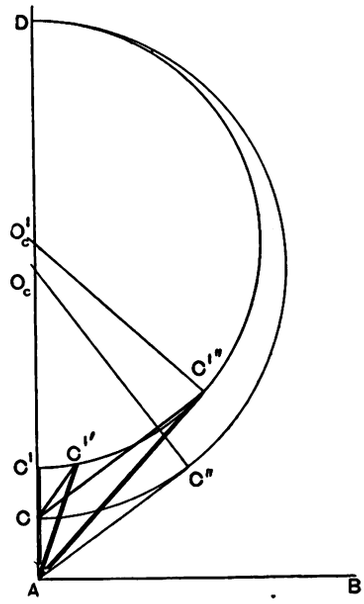

FIG. 5B.

We recognise that, for normal and for other loads, the power factor of the monophase motor will always be less than that of the polyphase motor, and considerably less for higher values. For this reason already we should strive to keep the leakage down, more so still than in the case of polyphase motors.

Torque.

The relations between slip and torque are defined by the equations—

For the polyphase motor, per phase, $Z = C \cdot \frac{a\,S}{1+b\,S+c\,S^2}$;

For the monophase motor, $Z^I = C \cdot \frac{a^I S}{1+b^I S+c^I S^2}(1-S)$, where

$$a = \frac{W_1}{W_2},$$

$$b = \frac{2}{f} \cdot \frac{W_1}{W_2},$$

$$c = \frac{1-f}{(1+f)^2 \epsilon_1^2 f^2} \frac{W_1^2}{W_2^2}.$$

For the constants a^I, b^I, c^I we have to substitute

$$W_2^I = \frac{W_2}{2} \text{ for } W_2 \quad \ldots\ldots \quad (3)$$

and

$$f^I = \frac{1}{3-2f} \text{ for } f. \quad \ldots\ldots \quad (5)$$

In order to establish a comparison between the motors of the examples (a) and (b), we will presume that they develop, as polyphase motors, the same power, the same normal slip S_{norm}, and the same normal torque Z_{norm}. We should then have, in both cases, $S_{norm} = 4$ per cent.

$$Z_{norm} = 1$$

$$\frac{W_1}{W_2} = 0{\cdot}80.$$

Examples of torque curves for both of these cases are given in Fig. 6.

For motor (a).—Z_a is the torque curve of the motor as *polyphase motor* ($\tau = 0{\cdot}01315$); Z_a^I the curve of the motor as *monophase motor* ($\tau^I = \frac{2\tau}{1+4\tau} = 0{\cdot}025$).

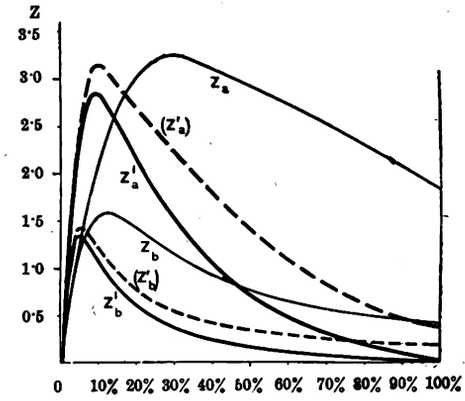

FIG. 6.

Z_a' would be the torque curve of the equivalent polyphase motor, as defined above, whose power curve would be given by

$$Z_a'(1-S) = Z_a^I.$$

For motor (b).—Z_b is the torque curve of the motor as *polyphase motor* ($\tau = 0{\cdot}0625$); Z_b^I the same of the *monophase motor* ($\tau^I = \frac{2\tau}{1+4\tau} = 0{\cdot}10$).

Z_b' would again be the torque curve of the equivalent polyphase motor whose power curve would be determined by $Z_b'(1-S) = Z_b^I$.

On comparing the curves Z_a^I and Z_a, and Z_b^I and Z_b, we observe that for small slips the torques of the motors of the two types vary in approximately the same manner. The torque of the monophase motor reaches its maximum, which is less than that of the other type, at a comparatively small slip. Beyond its maximum, the torque of the monophase motor decreases suddenly and rapidly; for a slip $S = 1$, the torque is zero. This rapid decline in the torque is brought about by the factor $(1-S)$, and further by the term $c^I S^2$ in the formula for Z^I. In case (a) $c^I = 92$, whilst $c = 11{\cdot}4$; case (b), $c^I = 330$, whilst $c = 70$.

Excessive Loads.

The capacity for taking excessive loads is: For motor (a), 2·84 ($S = 10$ per cent); for motor (b), 1·35 ($S = 5$ per cent).

These numbers demonstrate that the monophase motor behaves in this respect like the polyphase motor; the capacity increases when the stray decreases. The highest capacity will

Digitized by Google

be realised in the case of the ideal motor, where there is no stray field. For this ideal motor, there would be $\tau = \tau^I = 0$, $f = f^I = 1$, hence $c = c^I = 0$; the torque of the ideal motor would be $Z = C \cdot \frac{aS}{1+bS}$, and that of the *ideal monophase motor*

$$Z^I = C \cdot \frac{a^I S}{1+b^I S}(1-S) \quad . \quad . \quad . \quad . \quad (4B)$$

Fig. 7 traces this curve, likewise for $S_{norm.} = 4$ per cent. The capacity of the ideal monophase motor for taking excessive loads proves to be 5·25 (S = 30 per cent.). The assertion that the highest capacity will be obtained with the least straying is thus confirmed.* Electrical considerations as well as the mechanical efficiency render it advisable, therefore, to prevent so far as possible all straying; the rule holds for monophase motors still more than for polyphase motors.

Comparative Dimensions.

So far we have regarded the monophase motor as arisen from the diphase motor by the elimination of one of the two phases. In such a motor only half the space available would be covered with coils; the apparatus would give incomplete satisfaction only. The torque of the motor would be inferior to that of the original diphase motor. In other words, for equal power such a motor would have to be built *more than twice as large as a* polyphase motor.

In practice we shall either make use of a large portion of the space, leaving a small portion for auxiliary starting coils, or we fix coils all round, dispensing with automatic starting.

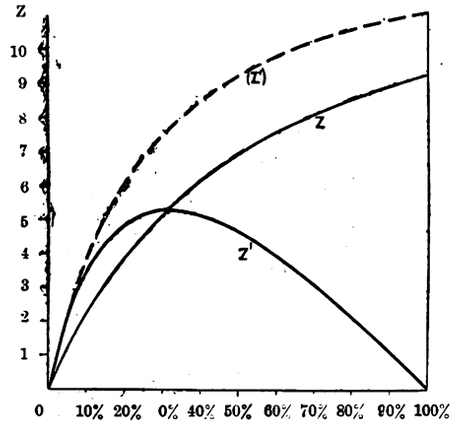

FIG. 7.

If we cover $\frac{2}{3}$ of the core with coils, we may consider the motor as a triphase machine, one of whose three feeders has been disconnected. If we cut out the third phase the current will be reduced to $\frac{\sqrt{3}}{2}$ of its value, and the power absorbed to

$$A_1^I = K\frac{\sqrt{3}}{2} i_1 = \frac{\sqrt{3}}{2} K i_1 = \frac{A_1^M}{2},$$

that is, to half the power of a polyphase motor. In other respects such a motor would resemble those considered above.

But we can keep the ampere-turns up to their full value by applying fewer turns of larger cross-section; the power can thus be augmented by $\frac{2}{\sqrt{3}}$. The motor would now do $\frac{1}{\sqrt{3}}$ as much as originally, and to have *equal power* at disposal the monophase motor would have to be designed $\sqrt{3}$ times as large as a polyphase motor.

A monophase motor which is fully wound may be likened to a diphase motor whose two windings have been connected in series. In this instance, the current would be reduced to $\frac{1}{\sqrt{2}}$ and A^I would become $\frac{A_1^M}{2}$. By judiciously arranging the coils, we can increase the current to $\sqrt{2}$ times its intensity and bring A_1^I up to $\frac{A_1^M\sqrt{2}}{2} = \frac{A_1^M}{\sqrt{2}}$. Here, again, the dimensions of monophase motors would have to be increased in the ratio $\sqrt{2}:1$ this time, in order to render the motor equal to a polyphase machine.

In general, we may say that *a monophase motor has to be constructed about half as large again* in order to do as much work as a polyphase motor.

On the whole we shall do well to make the monophase motor rather large. We need space for starting coils, and we have learned that the stray field should be reduced to its possible minimum; both conditions demand ample dimensions.

A monophase motor, which is correct as to the stray field, enables us to secure a strong starting torque with the help of an auxiliary phase. A glance at the curves Z_a^I and Z_a will show this. The auxiliary phase has to create a rotating field. The more perfect this field, the more the starting torque of Z_a will manifest itself.

* It has several times been stated (G. Kapp, "Transmission of Power," and others) that a considerable stray field is essential if the monophase motor is to do work. Those authors have fallen into an error when, in replacing the field of a monophase motor by two equal rotating fields, they did not consider that the one of these rotating fields tends to vanish for small slips.

THE CONSUMPTION OF CARBON IN AN ELECTROLYTIC CELL.

A noteworthy Paper by Dr. Alfred Coehn was recently read before the German Electrotechnical Association and printed in the *Elektrotechnische Zeitschrift*, from which we transcribe its essential argument. It deals primarily with the question whether carbon is competent to form ions and thus take active part in an electrolytic circuit; in other words, can carbon be caused to dissolve from an anode in the manner characteristic of a metal? An observation bearing on this point has been made by Bartoti and Papasogli, who found that on passing a current between carbon electrodes immersed in dilute sulphuric acid, both carbon monoxide and carbon dioxide appear at the anode, in addition to oxygen, whence it follows that the anode takes an active part and suffers oxidation. Dr. Coehn has attempted to extend this result by varying the concentration, temperature and current density so as to induce complete suppression of oxygen at the anode and its replacement by products of the oxidation of carbon, and he has so far succeeded that the gas escaping at the anode may consist substantially of 70 per cent. of carbon dioxide and 30 per cent. of carbon monoxide. A small quantity of oxygen (about 1 per cent.) is, however, usually present. In these researches it was noticed that at moderate temperatures disintegration of the anode occurs, and particles of carbon appear in suspension in the electrolyte. At higher temperatures this disintegration does not take place, but a significant coloration of the acid is perceptible. The liquid is at first yellow, and, in longer trials, becomes dark red and red-brown in colour. If this colour be due to dissolved carbon, it may fairly be concluded that the carbon is in the ionic state and dirigible by the current.

Seeing that the carbon thus present is not capable of decomposing water, the solution containing it should be in a condition to deposit the carbon at the cathode. Experiment bears out this deduction, for on substituting a platinum for a carbon cathode, carbon is deposited thereon in the manner characteristic of a metal. The first film of carbon exhibits the colours of thin plates, but as the deposit thickens it becomes black and graphitic. The phenomena of solution and precipitation can be obtained with various forms of carbon, including carbon rods for arc lighting and blast furnace coke.

After obtaining this remarkable result, Dr. Coehn took care to ascertain that the deposits formed in the manner described are really carbon and not some metallic impurity derived from the anode. The deposited material is insoluble in hydrochloric acid, slightly soluble in boiling nitric acid—recalling in that respect the behaviour of carbon in steel upon which is based the Eggertz colorimetric method of determining carbon. The film disappears completely on heating in contact with air. A determination by combustion (such as is practised in ultimate organic analysis) suffices to establish the belief that the deposit is chiefly carbon, associated, however, with

Digitized by Google

oxygen and hydrogen in the proportions to form water, and thus to be regarded as hydrated. This hypothesis is borne out by the behaviour of the film with strong sulphuric acid, which acts upon it much as if it were a carbohydrate.

The establishment of these facts led Dr. Coehn a step farther. To construct a cell capable of yielding electrical energy by the oxidation of carbon, it is necessary to find a cathode electronegative to the carbon, which has to function as anode.

Lead peroxide, in the form of a plate from a secondary cell, fulfils this need. When such a cathode is opposed to a carbon anode in a bath of sulphuric acid of the right temperature and concentration, a primary cell is obtained in which the carbon is the material attacked; a cell made in this manner gives a voltage of 1 03 on a circuit having an external resistance of 100 ohms. [Dr. Coehn does not state what fraction of the total energy appears as electrical energy.]

The question now arises, how far the results recorded are really due to carbon acting as a soluble anode. Platinum, when opposed to lead peroxide in a sulphuric acid electrolyte, becomes an anode, and gives a current which, however, decreases to a vanishing point as soon as the platinum electrode has acquired its complement of oxygen. No such arrest of the output of a carbon-lead peroxide cell takes place. Current is obtained until the cathode is exhausted, and the cell regains it efficiency when a fresh plate of lead peroxide is supplied.

Dr. Coehn ends his Paper by the following conclusions :—

1. It is possible to prepare a solution of carbon by electrolytic means.

2. Carbon can be separated from such a solution at the cathode.

3. A cell may be made having its soluble electrode of carbon.

PUBLIC LIGHTING BY ARC LAMPS.*

BY ANDRÉ BLONDEL.

The problem of the distribution and diffusion of light[1] from whatever source is an interesting study. If we consider only gas[2] or incandescent electric lamps, the question of diffusion has but a secondary importance, and that of distribution is the most prominent one; with the electric arc, on the contrary, good diffusion is quite as necessary as good distribution. The study of the electric arc thus brings the problem under consideration the most completely before us. I shall deal more especially with continuous-current arcs, seeing that they have, up to the present, been the most frequently used, though I shall treat in some detail of the problems of the alternating arc. I purpose making a close examination of the means actually employed in the production and utilisation of this source of light, indicating possible improvements. To this end it is necessary, first of all, to consider the arc lamps and accessories at present in use on public thoroughfares.

I.—GENERAL REMARKS.

LAMPS.

Notes on Arc Lamps from the Point of View of Production of Light.—An investigation of the construction and action of arc lamps is foreign to my subject. The lamps most generally used for public lighting, whether for continuous or alternating currents (Brush, Thomson-Houston, Brockie-Pell, Crompton-Pochin, Cance, Bardon, Siemens, Pilsen, Brianne, Pieper, Helios, Piette and Krizit, and Zipernowsky) are well known in their respective countries, and give almost equally good results so far as steadiness of working is concerned. The only point to which I would draw attention here is the economic value of arc lamps as instruments for transforming electrical energy into light.[3] This economic value may vary between wide limits according to the way in which the lamps are connected and the methods adopted in their management.

First as to the grouping of lamps; this question, properly speaking, belongs to the question of distribution of currents. I will only note in passing that to obtain steadiness in the arc necessitates the use of a resistance in series with it, and in consequence a certain loss in voltage. This loss varies according to the number of lamps in series and its *relative* value is less as the lamps are more numerous. For a single arc the loss may be 10 to 15 volts (that is to say, a voltage of 60 is necessary, although not more than 44 or 45 volts are consumed in the arc), while two arcs in series are easily run off 110 volts and four off 220-volt circuits (as is done in Paris). Again, on a five-wire system, with 440 volts between the outers, eight or even nine arcs can be connected in series, as is the case in the Avenue de Clichy. The corresponding loss of energy is, therefore, proportionately less, as we use a greater number of lamps in series. Hence, to obtain light in the most economical manner possible, the circuits should be arranged in this way. Distribution by constant current on the Brush, Thomson-Houston, and similar systems is, from this point of view, evidently most advantageous, but the lower efficiency of the special machines necessarily employed cancels the gain. Besides, it is more expensive to use special machines for arc lighting. It is far better where possible to connect up the public arc lamps to the existing circuits, taking care only to connect them in series between the conductors between which there is the highest

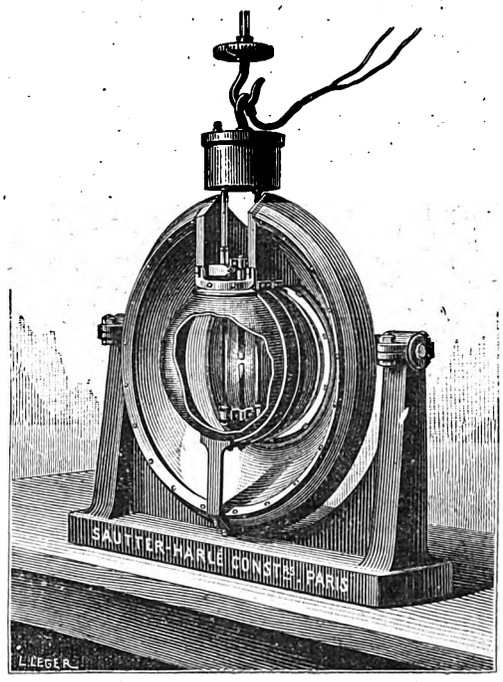

FIG 1.—Lumen Meter for Measuring the Total Luminous Flux of an Arc Lamp.

difference of potential. The alternating arc, to which I shall refer later, offers a slight advantage so far as stability is concerned, for it may be rendered stable by the use of impedance coils consuming but a small quantity of energy.

As to the management of lamps and sizes of carbons, I wish particularly to draw attention to the fact already mentioned in my "Theory of Public Lighting" (*The Electrician*, November 15, 1895, page 92), that the choice of carbons plays a most important part in the luminous output. For equal currents an increase in the length of the arc, or a diminution in the diameter of the carbons in continuous current arcs, increases the luminous flux produced[4], which is easily explained, seeing that more of the positive crater, the actual source of the light of the arc, is exposed. Prof. Carhart found with a certain lamp a maximum efficiency with 55 volts, and a decrease with any variation. I myself have observed similar results. But in practice other considerations limit us in this direction. On the one hand the length of the arc must not exceed, say, 4 to 5 millimetres, corresponding to 45 to 50 volts, for beyond that the arc becomes unstable, and gives a flaring arc, which consumes the upper carbon very rapidly, and may even damage the rods, &c. On the other hand, the reduction in the diameter is limited by the rapidity with which the carbons are consumed, which according to some writers[6]

* From *La Révue Technique*. Translated by Mr. John Hesketh.

[1] *See* "Street Lighting by Arc Lamps," by A. Blondel, *The Electrician*, Vol. XXXV., p. 646, *et seq.*

[2] This does not apply to the light from an Auer burner, for which diffusion is very desirable.

[3] I am for the moment only considering continuous-current arcs, reserving for later treatment the more difficult and very indifferently-treated questions involved in the consideration of the alternating arc; the conclusions will nevertheless be general

[4] It is not absolutely so with the alternating arc.

[5] See *Comptes Rendus du Congres des Electriciens à Chicago*, 1893.

[6] Marks. *The Electrician*, Vol. XXV., p. 150, June 13, 1890. It appears rational to expect the consumption to be inversely proportional to the section. The volume of the carbon consumed in a given time would then be independent of the diameter. This law seems to have been established by the numerous experiments made by M. Sabouret at the Gare d'Orleans.

Digitized by Google

varies almost inversely as the section. The advantage of small diameters is no longer doubtful. Herr Schreihage[7] who made the first experiments on this subject, found that the mean spherical candle-power is almost inversely proportional to the diameter of the carbon. For the purpose of making more rapid measurements on these points I recently invented an instrument "The Lumen Metre" (Fig. 1) which allows either the total luminous flux, or the hemispherical flux of an arc, to be obtained by one measurement. By the aid of this instrument, M. Jean Rey[8], for instance, obtained the following results when comparing a pair of carbons 21 and 13 millimetres in diameter with a pair of 14 and 8 millimetres.

Table I.

Amperes.	Volts.	With carbons 21 and 13mm.		With carbons 14 and 8mm.	
		Flux obtained in lumens.	Spherical intensity, pyrs per watt.	Flux obtained in lumens.	Spherical intensity, pyrs per watt.
20	44	7·900	0·70	21·330	1·92
25	44	9·430	0·68	33·830	2 43
30	45	12 270	0·72	46·330	2·72
35	46	28 100	1·38	61·330	3·03

These arcs are too powerful for ordinary uses, but the table clearly shows that the efficiency is trebled by the use of small carbons.

Similar results have been obtained from tests of the author as will be seen latter on.

Few engineers think of this fact, and those who are aware of it do not believe that the effect is so very marked, and therefore do not take any trouble to improve existing methods. These are inspired wholly by considerations of the consumption of carbon. It is imperative that a lamp shall work the longest nights without renewal of carbons. Hence, lamps burning from 14 to 16 hours are indispensable. To attain this object lamp makers first of all increased the stroke of the lamp and the length of the carbons, but they restricted themselves quite unnecessarily by keeping the carbon-holders within the ordinary globes, which are 35 to 40cm. in diameter. The result was that even after placing the source of light right at the top of the globe—a very unhappy expedient, since the eye instictively looks for it at the centre—they were not able to use very great lengths of carbon, and were consequently driven to the device of increasing the diameter. In France it therefore happens that carbons of enormous diameters are employed. For instance, on the main boulevards the carbons are respectively 17mm. in diameter and 250mm. long, and 12mm. in diameter and 220mm. long. On the Avenue de Clichy, we find 18mm. and 12mm. with lengths af 160mm. and 200mm. In both cases 10-ampere lamps are used. In England the same diameters are used in the Crompton-Pochin lamps. In America 16mm. and 12mm. are used. Under such conditions, the crater from which the light is emitted eats right into the positive carbon instead of being quite open, and is therefore too much hidden by the negative carbon. To show how unnecessarily great are ordinary sizes adopted for carbons, I may mention that in French electric lighthouses, where everything possible is done to obtain the best efficiency, carbons of 10mm. are used for currents of 25 amperes. That is to say, there is a current density eight times that in use on the Avenue de Clichy! The blame for this state of things does not rest with the engineers, but almost entirely with the lamp makers. They sometimes, it is true, make praiseworthy efforts to alter this absurd state of things, by increasing the length of carbons and slightly lessening their diameter. For instance, the 1891 type of the Bardon 16-hour lamp used 15mm. and 10mm. carbons, 280mm. and 260mm. long respectively. This tendency is an excellent one, and deserves to be followed, especially in the direction of the reduction in the size of the negative carbon. But enough has not yet been done, and we must not be satisfied until the diameters of carbons for 10-ampere lamps has been reduced to 10mm. and 7 or 8mm. The experience of Messrs. Siemens shows that 10-ampere lamps may be worked with 10mm. positive carbons and 3mm. negatives. The latter, however, is rather too small. More generally the maximum diameter of the carbon in millimetres should not exceed the number of amperes.

Two methods of obtaining this result are available. The first is to increase the travel of the carbon holders, and let the lower holder pass through the globe. Under these conditions a travel of 50cm. for each carbon is not impossible; carbons of this length can easily be made and used, as is shown by lighthouse experience, where carbons of 45cm. are used. All that would be necessary would be to arrange the lamps and their pillars accordingly, narrowing the lower ends of the guides so as to allow the carbon holders to pass into a small cylinder fixed on the lamp-post. If a lantern be used the arrangement is still easier, for nothing prevents the rods from dropping into the shaft of the lantern. A second solution, and one already applied with success in England and America, is to use double carbon lamps, the second pair of carbons being brought into use when the first pair is burnt out. We thus have a length of carbon double that of the travel of the holders.[9] We are indebted to the ever practical American for the first double-carbon lamps, of which the best known are the Thomson-Houston and the Brush (Fig. 2), which are also employed in many European installations. But unfortunately these lamps are non-focussing, so that the arc is sometimes at the top and sometimes at the bottom of the globe, In America, where clear glass globes are mostly used, the public are too dazzled by the arc to notice its position, but under diffusing globes this variation in the position of the arc is insupportable.[10] In England, where the movement in favour of double-carbon lamps has been well taken up, a much more satisfactory focussing lamp has been obtained. The Crompton-Pochin (Fig. 3) and Brockie-Pell lamps, between which there seems to be but

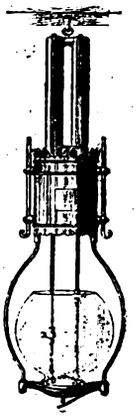

Fig. 2.—American Non-focussing Double-carbon Lamp.

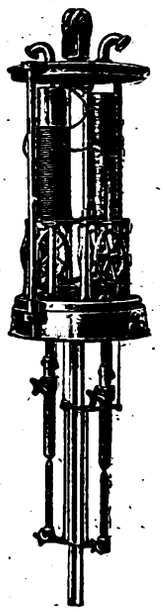

Fig. 3.—Crompton-Pochin Double-carbon Lamp.

little difference of principle, are constructed for either one or two pairs of carbons, for 16 or 32 hours. The following are the particulars of the carbons used in the 10-ampere lamp (which I shall always consider as the standard of comparison.

Table II.

Type of lamp.	Carbons.				Duration in hours.
	Positive.		Negative.		
	Diameter	Length.	Diameter	Length.	
Crompton-Pochin	18	300	12	200	16 or 32
Brockie-Pell	13	360	12	220	16 or 32

It would seem, however, that the real advantage of the double-carbon lamp is not yet understood; the object with which they are now principally used is to reduce the number of attendances of the lamp trimmer from once daily, as in Paris, to once every two days. It appears to me that the aim in view should be quite different. Double-carbon 16-hour lamps with carbons of reduced section should be used, and the carbons should be changed daily.[11] An

[7] *Centralblatt für Electrotechnik.*

[8] *Bulletin de la Société Internationale des Electriciens*, May, 1895.

[9] Even assuming that carbons of the same large diameter are still used this solution of the problem, which complicates the mechanism of the lamp a little, has a practical advantage over the preceding, for it allows the carbons to be used up to the end without any fear of the lamp going out when most wanted. With the ordinary system it is either necessary to use different lengths of carbon for different seasons, as is done in some districts of Paris, or to carefully preserve the partly burned carbons during each night of a given month to be used up during one night six months later, as is done in other parts of Paris. We can easily see the complications which it involves. With double carbon lamps, on the contrary, the same kind of carbons are always used, the interval between their renewal being the only variable.

[10] It is, of course, understood that I am speaking here of lamps with two *independent* pairs of carbons. The others, which were detestable, are happily scarcely used at all at the present time.

[11] In this case the advantage of using the carbons to the end is lost.

Digitized by Google

enormous quantity of light would then be gained without the service being in anyway complicated, and with no increase in expense at all comparable with the benefits obtained. In France, unfortunately, no steps have been made in this direction, for there are no double-carbon focussing lamps on the market.[12] Surely the day will come when engineers will fix in their specifications on a maximum allowable diameter of carbons; or, which will amount to the same thing, a minimum current density. The contractor will then be limited in his choice, and must choose between the two solutions we have just indicated, or some other attaining the same result.[13] It is no exaggeration to say that this simple change in the size of carbons would allow more light to be obtained from an 8-ampere arc than is now given by one taking 10 amperes.

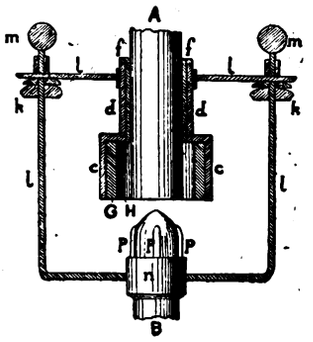

FIG. 4.—Hardtmuth's Carbon Economiser for Continuous-current Arc Lamps. H, Air Chamber. *f* and G, Lining of Refractory Substance. *c*, *d*, Metal Sheath.

M. Sabouret, of the Compagnie d'Orleans, who has long taken an interest in the question of the important waste caused by the use of single-carbon lamps for railway station lighting purposes,[14] has invented an ingenious arrangement for easily changing almost all the existing types of single into double-carbon lamps without adding to the ordinary mechanism, increasing the economy of the carbons from 60 to 90 per cent. Fig. 5 shows M. Sabouret's invention applied to a Siemens ribbon lamp, made in France by the Société Alsacienne de Belfort, and in use on the Avenue de Clichy in Paris and on the main boulevards. The two drums C_1 and C_2 are loose on the spindle A, which receives the regulating motions. The arm B is fixed to the spindle A; it carries two projections D_1 and D_2 moved by springs which encounter the studs T_1 and T_2 on the drums D_1 and D_2. In Fig. 5 the arrangement is shown at the moment when the ribbon 1, nearly at the end of its stroke, comes in contact with the trunnion arm T. The spindle A is carried round by the weight of the carbon attached to band 1. Drum C_2 does not unroll, its band being gripped by T; moreover, during the rotation of the drum C_1, the projection D_2 escapes the stud T_2 of the drum C_2. But from the moment when band 2 is freed, drum C_2 is carried round by its carbon, and it, in its turn, rotates the spindle. Band 1, when it has run its course, keeps drum C_1 immovable. The Siemens lamp is non-focussing, but the same appliance can be used with focussing lamps. MM. Sautter et Harlé are going to apply it to their brake lamps, such as are used on the Sceaux line. It may, therefore, be hoped that before long we shall see some trials of double-carbon lamps for public lighting in France.

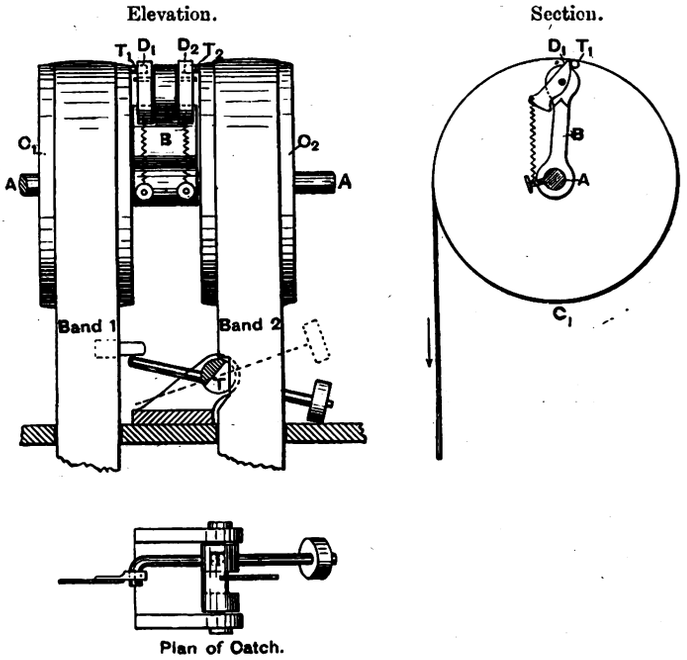

FIG. 5.—Sabouret Arrangement for Transforming Single into Double-carbon Lamps.

There is still another point to be discussed here, and that is the current to be used. Large arcs give a better efficiency than small ones. The subject was treated superficially in my "Theory of Public Lighting" (*The Electrician*, November 15, 1895, page 89), but sufficient experimental data is lacking to enable me to discuss the subject in the present paper. I intend to discuss it fully in a near future.

(To be continued.)

Arc Lighting by a Tramway Power Station.—A somewhat interesting piece of street arc lighting came into operation in Paris at the beginning of the month. The thoroughfares concerned are the Avenue de la République and the Avenue Gambetta, and the lighting is carried out by 108 Eck arc lamps. Along a portion of the Avenue de la République the posts are placed on refuges in the middle of the road 40 metres (130ft.) apart; elsewhere they are arranged in *quincunx* on the pavements. Current is supplied from the power house of the Paris-Romainville electric tramway, the lamps being nine in series across the 500 volt mains. In the base of the pillar of the leading lamp of the series there is a special switch and regulating rheostat controlling the group; in addition each lamp is provided with a resistance of 4 ohms, which is automatically switched into circuit should the lamp by any chance fail,

---

[12] Since writing these lines Messrs. Tresel, 7, Rue du Perche, have introduced a simple and practical double-carbon lamp, some of which are already in service at the Lyons and Orleans railway stations. The mechanism is the same as for a single pair of carbons; the two pairs are parallel, but one of the carbons of the second is out of alignment, and only comes into line after the first pair has burnt out.

[13] Other solutions to increase the life of carbons without lengthening them have been suggested. Flat carbons have been tried, offering a large surface without any additional thickness, but with these carbons the arc constantly shifts, and the result is bad. Carbon discs placed at right angles to each other, and slowly revolved at the same time as they approached have been tried. The arc naturally occurs at the shortest gap, so that its position is very definite, but such an arrangement is too delicate. The shielding of the light plays too important a part, and the continual movement of the incandesced particles evidently lowers the efficiency. Another interesting method which has often been tried is to enclose the arc in a globe as air tight as possible, so that the combustion of the carbons may be retarded. This arrangement, which has already been invented many times, and which was last invented by Mr. Marks in America, is very attractive. In practice it was found that the carbons were not shaped so evenly, and that the globe was rapidly covered with a non-transparent deposit due to the condensation of the saline residues contained in the carbons, and of the carbon vapour from the arc. Even when pure carbons are used this last inconvenience is not overcome, so lamps fitted with sealed globes have not been a practical success. The life of carbons has been lengthened by dipping them in a bath of metaphosphoric acid, which retards combustion in a very marked manner, or by electrolytically coating them with copper or zinc, which at the same time augments their conductivity. This last device markedly increases the price of the carbons. As to the results obtained, opinions are very divided. My own experience is rather unfavourable, the copper plating causing accidental extinctions; if, in fact, a drop of copper falls through the arc and volatilises, the current suddenly jumps by way of the low resistance path so formed and leaves the arc, which goes out. Messrs. Hardtmuth have recently placed on the market a protection for the positive carbon consisting (Fig. 4) of a tube of refractory matter encircling the end of the carbon and preventing combustion. The economy is very great, but there is a difficulty in keeping the tube always at the desired height. According to trials made at Vienna (*Elektrot. Zeit.*, November 15, 1894), the luminous flux is very little reduced by the use of this instrument, while the consumption of carbon varies in the following proportion for a 6-ampere lamp.

	+ carbon (16mm.)	− carbon (11mm.)
Without protector.....	14·1cm.	15·5cm.
With protector	4·9cm.	10·0cm.

These figures are of course to be accepted with reservations, being the result of the inventor's trials. Not being able to procure the apparatus in France, I have not been able to verify the results. The device appears to have given good results in the trials in the Edison sector.

[14] The question of the losses on account of carbons is not important in towns where 1fr. or more is paid per kilowatt-hour for the energy, but it plays a very important part in railway station lighting, where the energy is produced at a much lower figure. At the Gare d'Orleans, where the cost of energy is less than 0·25fr. per kilowatt-hour, the cost of carbons is one-quarter or one-third the cost of fuel.

Crompton; William Sturgeon; and Dr. John Hopkinson, F.R.S., have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)

ENGINEERING CHEMISTRY.

Much has been said and written lately about the interdependence of chemical and electrical theory, and on the connection between chemical phenomena and the electrical condition of atoms. It may be of interest, therefore, and it is certainly natural, to turn our attention to the practical side of the matter, and to examine some of the relationships which exist between chemistry and electro-technics and engineering. For convenience we shall include electro-technics in the greater subject of engineering, of which it is naturally a part. The oft-repeated definition of engineering which has been immortalised by the Institution of Civil Engineers in its Charter would become tiresome from frequent repetition if it were not so profoundly true. "The art of directing the forces of Nature for the use and convenience of man," covers every branch of the profession, except perhaps the military branch, which someone has profanely defined to be "the art of directing the forces of Nature for the abuse and inconvenience of the other man." We have only to compare an accurate definition of chemistry with that of engineering just given, in order to discover that technical chemistry falls completely under that head. If chemistry is the science of the composition of substances and the changes which they undergo, it is to be noted that to these very changes mankind owes the manifestation of some of the most potent "forces of Nature," and also that almost all the forms of energy in Nature are applied in bringing about commercial chemical reactions "for the use and convenience of man." Thus does chemistry aid engineering on every hand; and engineering repays the debt by affording means for carrying out chemical industries on a commercial scale.

Digitized by Google

A survey of the various ways in which engineering is aided by chemistry will show that these fall under two heads: first, the chemistry of energy; second, the chemistry of structural materials. By the chemistry of energy we mean those processes by which any form of energy is chemically generated or stored for useful purposes. Practically the whole of the energy used in the industries of the world is derived from chemical processes directly under human control. The estimation of fuels, their preparation for use in boilers and gas engines; the detection and treatment of injurious and of valuable constituents; the selection of boiler waters and their treatment when unsuitable; the choice of materials for primary and secondary batteries, are instances of the influence of chemistry in this relation.

The chemistry of structural materials is even more varied and extensive than that of energy. In an excellent work, entitled "Chemistry for Engineers and Manufacturers," by Messrs. Bertram Blount and A. G. Bloxam, which has recently come into our hands, the authors aptly state that "the permanence of a given structure and the degree in which it is fitted for its use do not depend exclusively upon the mechanical strength of the materials composing it, but are largely influenced by the chemical composition of these materials and by the chemical conditions to which they are exposed." We are not now concerning ourselves with chemical processes for manufacturing materials, but with the light which chemistry throws upon the suitability or otherwise of any given material for any given purpose. To cite a few examples: we are enabled to select bronzes and other materials for the bearings of shafts in machinery, and lubricating materials which shall not act chemically upon them; we decide upon materials for the foundations and superstructure of our buildings according to the chemical conditions to which they will be subjected; preservative compounds, coatings, electro-plating, &c., owe their existence largely to chemical considerations. The art of directing that terrible force of Nature—decay—so that it shall not render our machinery or our buildings useless, is not the least important branch of engineering.

Turning now to the contrary side of the question, we discover no less widespread activity in the assistance which engineering affords to the processes of commercial chemistry. Superfluous it might seem to mention particularly the aids of the building engineer, in the construction of furnaces, vats, &c.; or of the mechanical engineer, in adapting boilers, furnaces and other plant for directing energy to the chemical process in hand. Let us narrow the consideration down somewhat, and speak only of the applications of electrical engineering to these ends. And here, too, it will be convenient to classify our matter under two heads, each relating to a distinctly different type of chemical process. We refer to what are technically known as the "wet processes" and the "dry processes." Formerly, commercial chemistry was carried on exclusively by wet methods, by electrolysis from aqueous, alkaline or acid solutions at ordinary temperatures, or at any rate not at furnace temperatures. The electro-plating of wrought goods constituted the principal branch of this industry; but at a comparatively early date Messrs. Siemens and Halske introduced an electrolytic process for obtaining copper from the pyrites, the ore having been previously leached with a solution of ferric sulphate; and one of the earlier applications of electricity to metallurgy by the wet way was in the extraction of gold by cyanide processes. At the present time, the number and importance of the wet electrolytic processes for extracting metals and for the manufacture of chemical compounds, such as caustic alkali and bleach, chlorate of potash, &c., rank much higher than formerly; but it is in the direction of dry processes that the most startling of recent developments in electro-chemistry have taken place. An interesting and promising development of electrolytic wet process in sanitation, however, should not escape notice. We refer to the Hermite process, which has met with considerable success at Ipswich and in other towns. Among electrolytic dry processes we may mention the extraction of aluminium from its ores in the electric furnace, and the discovery and subsequent manufacture of carborundum and calcium carbide by means of the same furnace. Electrical dry processes in metallurgy have, however, been confined principally to the production of metals which have hitherto resisted extraction by ordinary furnaces, the high cost of electrical energy having rendered prohibitive its application to older and more common metallurgical work. Perhaps the time may come when the work of the blast furnace, the puddling hearth and the converter will everywhere be done by the heat of powerful electric currents; but the barest calculation of cost leads one to fear that that time is still a long way in the future.

But although there are many metallurgical and other chemical processes which for some time may be much more cheaply performed by the aid of ordinary furnaces than by electrical methods, there are probably not a few as yet untouched which would well repay development by the electro-chemist. Unfortunately the genus "electro-chemist"—as a commercial factor—is a rarity. What with secondary battery improvement and electro-chemical manufactures, there is a deal of useful work he might be doing; and we hope he will speedily increase and multiply. Prof H. E. Armstrong, in his recent Presidential Address before the Chemical Society, complained, in regard to a certain point of electro-chemical theory, that it had been ignored by chemists, adding: "Unfortunately the physicists have also neglected this subject, having apparently left it to the chemists; . . . the result is blank ignorance of all that is fundamental with regard to such matters on the part of both chemists and physicists." An exact and deplorable parallel to this is to be found in regard to many of the possibilities of commercial electro-chemistry. The chemist is ignorant of the electrical aspect of the question, and has left it to the electrical engineer, who, in turn, has consoled himself with the reflection that if anyone ought to know anything about chemical processes it should be the chemist. The result, as Dr. Armstrong put it, has been "blank ignorance"—and fertile ground untilled. This state of affairs is no doubt a consequence of the modern tendency towards specialism. Ten half-starved men may nowadays know perfectly ten facts, which if all known to any one of the ten would enable him to "make his pile." The extensive field of commercial electro-chemistry adjoins the overcrowded regions of electric lighting and power supply; and all that is required to develop it is that there should be a coalescence of technical knowledge of chemistry and electricity.

REVIEW.

Chemistry for Engineers and Manufacturers. By Bertram Blount and A. G. Bloxham, FF.I.C. and FF.C.S. Vol. I., Chemistry of Engineering, Building and Metallurgy. (London: C. Griffin and Co., 1896.)

The volume before us is the first of a two-volume treatise on the chemical technology of engineering and manufacturing operations. The present volume deals with the chemical principles of mechanical engineering, building, and metallurgical and other chemical operations. A second volume, shortly to be published, will treat of many of the manufactures

Digitized by Google

which have a distinctly chemical basis, and will therefore supplement the present volume on the descriptive and practical side. A reader of the volume before us could scarcely fail to notice the convenient and pleasing order in which the matter throughout is arranged, and the perspicuity of the style adopted by the authors. The nature and scope of the subject have rendered condensation necessary; but the subject matter appears to have lost nothing in clearness and precision from the compression to which it has been subjected; while the judicious selection of material of prime importance, and the equally judicious rejection of secondary matter and questions of side issue, are apparent upon nearly every page. Here and there we notice exceptions—not, however, of great importance—where the authors have departed from the general simplicity of style; as, for example, where fuel is defined as "any substance capable of exothermic oxidation with sufficient rapidity to leave an available balance of energy after the leakages of energy surrounding the point of combustion (*e.g.*, radiation, convection and conduction) have been supplied." In attempting to give a definition, the authors have merely summarised the behaviour of fuels; and the use of the word "combustion" begs the question entirely, and carries the definition in a circle. Moreover, in practice, when the combustion of a fuel is proceeding at a steady rate, the temperature is constant and there is no "balance of energy after," &c. Exception may also be taken to the authors' use of the phrase "yield point" in place of the more common term "elastic limit." There seems to be no reason why a material under stress should be said to "yield" at the elastic limit any more than under a greater or lesser stress than occurs at that point; while the term "elastic limit" has the advantage that it fixes the limit of stress, on the removal of which the material recovers practically perfectly from its deformation.

Introductory matter fills the first half of this volume, and deals with the chemistry of constructive materials, of the sources of energy, of steam raising, and of lubricants and lubrication. The second part of the volume is entitled "Metallurgy," and deals with the treatment of metalliferous ores, iron and steel manufacture, the processes for the production of commercial copper, lead, zinc and other metals, and the parting of gold. It is with the first part of the volume that the constructive engineer, whether electrical or otherwise, is chiefly concerned; while the metallurgical section will interest that side of the electrical profession which is devoted to electrolytic production of metals. The first chapter in Part I. shows the chemical properties of building materials, such as stone, brick, concrete, and iron and other metals; and it should form a valuable guide to the choice of materials in constructive work, and to the treatment of them in regard to the chemical forces of decay, &c., to which they are liable to be subjected. In Chapter II. various fuels are discussed, in regard to their preparation for commercial use, combustion and thermal value. In the section on "Liquid Fuel" a diagram of a Priestman spray-maker is shown, in a connection which would naturally suggest that this form of spray-maker is used where liquid fuel is burned for steam raising; whereas such a nozzle is quite useless for the purpose. Fuel gas generated from fixed solid fuels receives a considerable share of the authors' attention, and the various processes of its manufacture and use are accurately and clearly described. Primary batteries, as a chemical source of energy, are dealt with in this chapter; but the work gains little in real value by the few pages devoted to this subject. In the chapter on "The Chemistry of Steam Raising," we find a collection of useful information about boiler waters and their treatment for hardness, saltness, &c., and about the use of anti-incrustators. Steam users are warned that these latter "all are sold at prices bearing but a remote relation to their intrinsic values," a kind of negative advertisement; but the authors appear to have omitted to give the important advice that these compounds should not be introduced directly into the boiler, but into the feed-heater or economiser. The electrical branch of metallurgy occupies but a small proportion of Part II., no doubt chiefly because electro-metallurgy has so scantily supplanted older methods of separating and refining metals. The chief references to the electrolytic extraction of metals occur in the section on "Copper," where the Siemens and Halske wet process is described; and in the section on "Aluminium," where a short account of the electrolysis of fused cryolite is given.

The letterpress and illustration of this latest contribution to the literature of technical chemistry are as well executed as the literary matter, and they enhance the value of a treatise which should prove decidedly useful to the constructive engineer and electro-chemist.

THE REGULATION OF PRESSURE AND THE REDUCTION OF LIGHT LOAD LOSSES IN ALTERNATING CURRENT SYSTEMS OF ELECTRIC SUPPLY.*

BY E. W. COWAN AND ALFRED STILL.

On account of the greater facility with which the pressure can be maintained on a system of distribution when the supply is a high-tension one, provision for its regulation has come to be somewhat neglected in this country. The standard of permissible variation of pressure with a low-tension system has not been a high one, and because with a high-tension supply it has been found easy to improve upon this, few efforts have been made towards the attainment of a higher standard. But with the heavier loads of to-day, and the advantage of our more complete knowledge of alternating currents, we should not rest satisfied with so low a standard; and complaints from consumers connected to the tail end of long distributors of the falling off in their light at times of heavy load, when its full brilliance is most desired, should belong to the history of the past. We can do better and we ought to. The object of the first part of this Paper is to set forth what we believe to be the best methods of maintaining constant pressure in all parts of a distribution system under varying conditions of load.

The first point to which attention must naturally be paid is the arrangement of the mains and transformers. This subject has already been dealt with to some extent before this Society by Mr. Clirehugh and Mr. Rider; but as each district must be considered on its own merits, it is not possible to formulate any definite rules. There are, perhaps, four systems open to us:—

1. High-tension distributors with transformers on consumer's premises.
2. Feeders in connection with high-tension distributors, and transformers on consumer's premises.
3. Feeders with transformers in sub-stations and low-pressure distribution.
4. Feeders with transformers in street boxes and both high and low tension distributors.

From the point of view of the subject of this Paper—viz., the regulation of pressure—the first of the above systems is the worst and the last one the best. It is on the relative advantages of the third and fourth systems that we should like to offer a few remarks.

Sub-stations with banks of transformers have become very popular; but we are inclined to think that their advantages are somewhat overrated, and that a cheaper, and in some respects more efficient arrangement, is to space out the transformers under the footway in the manner indicated at D, in Fig. 1. With this arrangement a much better regulation can be obtained than the low-pressure distribution system shown at C. It has the further advantage of simplicity in the first laying of the mains when the distribution of the load is uncertain. Most of us have been surprised when a station has been running for some time to find that our lamp connections have not distributed themselves according to our expectations, and that we have heavy cables lightly loaded and light cables heavily loaded. With this system it is simple and inexpensive to lay both high and low tension cables of large enough capacity for the ultimate requirements of the district. The transformers, which may be of uniform size, are fixed according to the position and amount of load as it arises; the final result being that transformers are close together where the load is heavy and comparatively remote in those positions where the demand is small. It may be argued that many transformers of a small size cannot be so efficient as a small number of larger size; but 12 to 15 kilowatt transformers may have a very high efficiency, and they are more readily handled than the very large sizes often fixed in sub-stations.

If underground switches are arranged to connect the low-tension service mains of one transformer to those of the transformers on each side of it when required, it will be possible to remove a transformer without interfering with the supply. And if similar switches are fitted at intervals in the high tension main, a fault in the cable can readily be cut out and the supply continued in the whole district fed by this main, with the exception of the particular length which contains the fault. Such underground switches can be made at a low cost, and will work quite satisfactorily.

* Paper read before the Northern Society of Electrical Engineers.

Whatever system may be adopted, it is certain that feeders will form part of it, and the important question arises as to what cross section they should have. Apart from the question of regulation, there can be no doubt that they should be proportioned in accordance with Thomson's law; but here a difficulty arises—the loss of pressure will frequently be so great, that, at times of full load, uniformity of pressure cannot be maintained at the feeding points, unless all the feeders are of the same length and subject to corresponding fluctuations of load; a condition which does not obtain in practice. It follows, therefore, that a regulating device must be connected to each feeder, preferably at the generating station end, or inequality of pressure at the feeding points will result. The other alternative being to lay feeders which are uneconomical on account of their large cross-section and corresponding first cost. Mr. Crompton, we think, makes too much of "efficiency of distribution," this being a question which cannot properly be dealt with, except in connection with first cost.

We propose now to describe a simple graphic method of determining the sectional area of feeders according to Thomson's law, as the usual formula needs some modification to adapt it to cables of which the insulation bears a large proportion to the total cost, and which do not carry a constant load. We will afterwards deal with the various regulating devices which are available at the present time for compensating for the drop on the feeders.

Feeders.—The most economical cross-section for a feeder depends upon two things only—the first cost of the cable, and the cost of production of the energy lost in it on account of its ohmic resistance

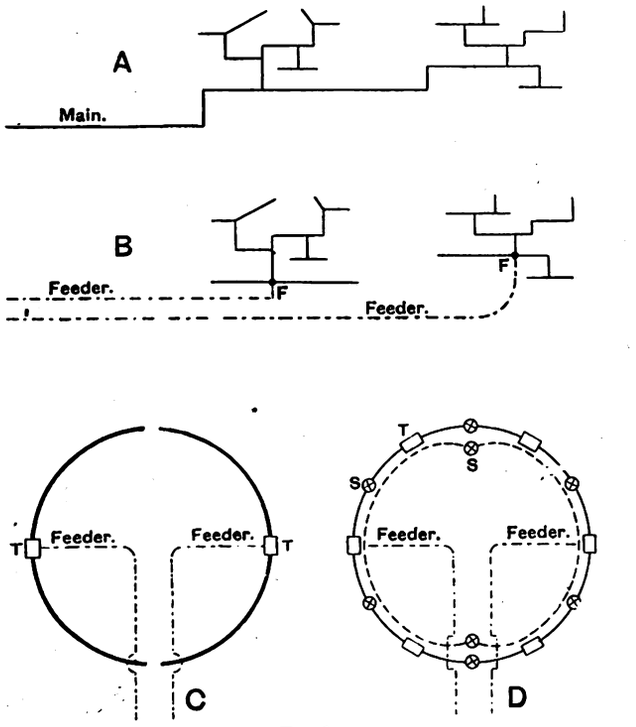

FIG. 1.

Thomson's law, which takes into account the annual cost of the watts lost in the conductor, and the allowance for depreciation and interest on first cost of the cables, may be expressed as follows:—

The most economical section of a conductor supplying electric current to a distance is such that the annual allowance for interest and depreciation on original cost of the cable will be equal to the annual cost of the energy wasted in overcoming its ohmic resistance. The cross-section should, therefore, be determined solely by the current which it has to carry, and not by its length, or an arbitrary limit of the percentage full-load drop in pressure—the drop, even if considerable (and it is not likely to be so on a high-tension system), must take care of itself.

There are possibly two reasons why Thomson's law is not more generally followed in calculating the sizes of feeders for systems of electric light supply:—

Firstly—because it applies only to bare conductors, of which the cost per mile may be taken as being proportional to the weight of the copper, and therefore to the cross-sectional area; and secondly—because it assumes the current to be constant from one year's end to the other: a condition of things which unfortunately has not been realised by electric supply stations. Although Thomson's law, in its usual form, is not directly applicable to existing conditions, the *spirit* of it should never be deliberately neglected. All that we have to attend to is this: to see that the annual cost of the energy wasted in a mile of the feeder, added to the annual allowance (per mile) for depreciation and interest on first cost shall be a minimum. With regard to the question of varying current, this is easily dealt with. The energy lost in a given cable depends upon the square of the current and the time during which the current is flowing. If a cable conveys a current, C, only 12 hours out of the 24 hours, then the energy wasted per day is only half what it would have been had the current been flowing continuously, and the watt hours may be expressed as $12 \times c^2 \times r$, or as $24 \times \frac{1}{2} c^2 \times r$, and it is evident that in working out the energy lost per annum in the cable, we have to multiply the resistance, not by the square of the *maximum* current which the cable will carry, but by the mean value of the squares of the current during the year.

From measurements taken on actual load diagrams it would appear that, in the case of electric light supply stations having a small all day load, the full load or maximum current is from two to three times as great as the mean square value of the current taken for the whole year; this proportion depending upon whether the capacity of the feeder is appreciable or not, and also upon the nature of the districts supplied. It is evident that this multiplier can easily be worked out from a few typical load diagrams.

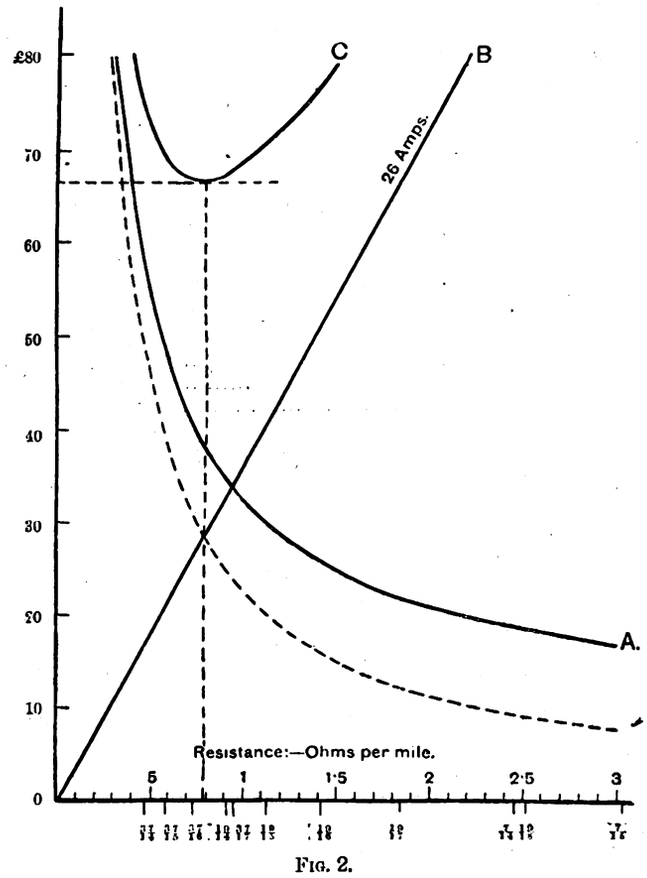

FIG. 2.

The following example and the diagram Fig. 2 will make it clear how the proper size of cable may be worked out in actual practice. And first it should be understood that it is the cost of the cable only on which the percentage for interest and depreciation should be taken, because the cost of trenching and laying, or drawing into pipes or culverts will be practically constant, and unaffected by the exact cross-section of the copper in the cable. Let us suppose that 10 per cent. is to be allowed for depreciation and interest on capital spent; then, in the diagram Fig. 2, where the horizontal distances represent resistance in ohms, and the vertical distances represent money, plot the curve A, which gives the relation between 10 per cent. of the cost per mile of the cable (taken from the maker's price list) and its resistance in ohms per mile (go and return)—this curve, which has been plotted from actual prices for concentric cables by a certain firm of well-known manufacturers is not a rectangular hyperbola as it would be if Thomson's law were to hold good. The dotted curve is a true hyperbola or the curve which makes the cost universally proportional to the resistance of the cable, and inspection of these two curves will show how the cost of the (insulated) cable is proportionately greater for the smaller sizes.

Now calculate the cost of the C^2R losses per mile of cable for any particular value of the resistance, and draw the straight line O B which will give us this cost for any other resistance of cable.

Digitized by Google

In this diagram the losses have been calculated on the assumption that the current is 26 amperes, and that the cost of production is 1½d. per unit. It is evident that this must be taken on the low side, as during the lifetime of the cables the works cost of the unit may be expected to be reduced.

By adding the ordinates of the curves A and B, the curve C is obtained, whose minimum value corresponds with a resistance per mile of 0·78 ohms. The nearest cable to this (on the small side) is 19/14, and this, if the cost of production of electrical energy and the probable current have been estimated correctly, is the proper size of cable to use, whatever may be its length or the voltage required at the feeding point.

Assuming the maximum value of the current to be three times the square root of the mean square value, and the length of the feeder to be one mile, the "drop" at full loads would be :—$78 \times 0{\cdot}91 = 71$ volts.

Capacity.—The effect of capacity in a system of concentric mains is to increase the current entering the cable at the alternator end, although the current leaving the cable at the far end will, of course, depend only on the pressure and lamp load at that end.

In the long concentric feeders the capacity current should therefore be taken into account, especially as its effect in increasing the total current is more marked at light load than at full load. It is easily calculated with sufficient accuracy by the formula $C = 2\pi n K V$, where K = the capacity in farads,

n = the frequency in periods per second,

V = the mean voltage.

It must be remembered that this current is not in phase with the main current, but one-quarter period in advance of the impressed volts. Hence, if C = 10 amperes this will be the current indicated by the feed ammeter on open circuit. At full load, with 60 amperes taken out at the far end, the current read on station ammeter will be the square root of $60^2 + 10^2$, or about 61 amperes. The following capacities of concentric cables have been kindly furnished us by the makers, and may be found useful in estimating the probable value of the capacity current in a given system of mains :—

Capacities per mile (inner to outer) of 19/18 concentric cables :

British Insulated Wire Company (paper)...	0·31 microfarads.
Glover and Co. (vulcanised rubber)	0·615 ,,
Ditto (diatrine)	0·315 ,,

Drop on Feeders.—Having fixed the cross-section of the feeders and calculated the full load "drop," it will generally be found that the latter is considerable on the long feeders and inappreciable on the short. Some methods of dealing with this difficulty must, therefore, be adopted which will allow of each feeder being independently regulated, as, if we raise the pressure of the 'bus bars to compensate for the drop on the long or heavily-loaded feeders, we shall be at the same time increasing the pressure at the feeding points which are nearer the generating station, or at those which are more lightly loaded. There are three methods of effecting the desired result, all equally efficient in respect to regulation, but differing widely in their efficiency in respect to economy :—

1. Raise pressure of generators until 'bus-bar pressure equals that required for the feeder with the largest drop, and switch more or less resistance into all the other feeders to absorb the consequent excess of pressure above that required.

2. Same as above, but use variable choking coils instead of resistances.

3. Adjust pressure of generators until 'bus-bar pressure equals that required for the feeder with the least drop, and by means of a special induction apparatus add pressure as required to the remaining feeders.

Very few words will be required to show the great economical advantage of the third method over the two others. In the first plan the resistances dissipate energy which has cost fuel to produce, and so rob the station of a percentage of its output at the time of maximum load ; a serious disadvantage in itself. The second plan is much more economical than the first. But choking coils are not like transformers—the induction and consequent loss in the iron being very much higher on account of the E.M.F. of self induction being ¼ period out of phase with the main current. For a 10 per cent. reduction of pressure the amount of the induced volts will be over four times the volts deducted. But apart from this it will be readily seen that the generation of the E.M.F. by the dynamo and its subsequent destruction by the choking coils cannot be an economical arrangement, accompanied as it must be by the losses of a double operation. The third plan is free from the above objections —the volts required to compensate for drop are added when and where required, and the generators, being worked at a low pressure, work more economically. Without analysing the question, common sense tells us that such a plan is better engineering. When we want to light a part of a building, we do not think it right to switch on all the lamps and screen the light from those parts not needing illumination, and there is no more reason for regulating feeders upon a similar principle.

The use of a regulating transformer for this purpose was first brought under our notice by Mr. J. H. Rider, who designed and specified such an arrangement for the Bolton Corporation Electricity Supply Station. The principle was not, however, new, and it may be of some interest to trace its development. As far as we have been able to ascertain, the late Mr. J. E. H. Gordon was the first to make use of the idea of augmenting the E.M.F. of a circuit by connecting in series with it the secondary coil of a shunt transformer. In Fig. 3 this plan is illustrated. He terms the apparatus a "hitcher-up." Part II. on the same diagram shows a feeder-regulator designed by Mr. Gisbert Kapp ; this apparatus is the same as Gordon's, but is provided with a means of varying the augmentation. A segment switch is arranged to cut out the primary coils as desired ; as the coils are cut out the E.M.F. generated in the secondary is, of course, increased. Fig. 3, part III., shows the principle of an apparatus designed by Stillwell in America, and manufactured by the Westinghouse Company. This design is similar to Kapp's, and was indeed also suggested by him, the only difference being that instead of primary coils being cut out secondary coils are switched in.

IV. and V. at the bottom of the diagram illustrate another design of Mr. Kapp's, which was intended to get over the difficulties of a high-tension segment switch, with its necessary devices

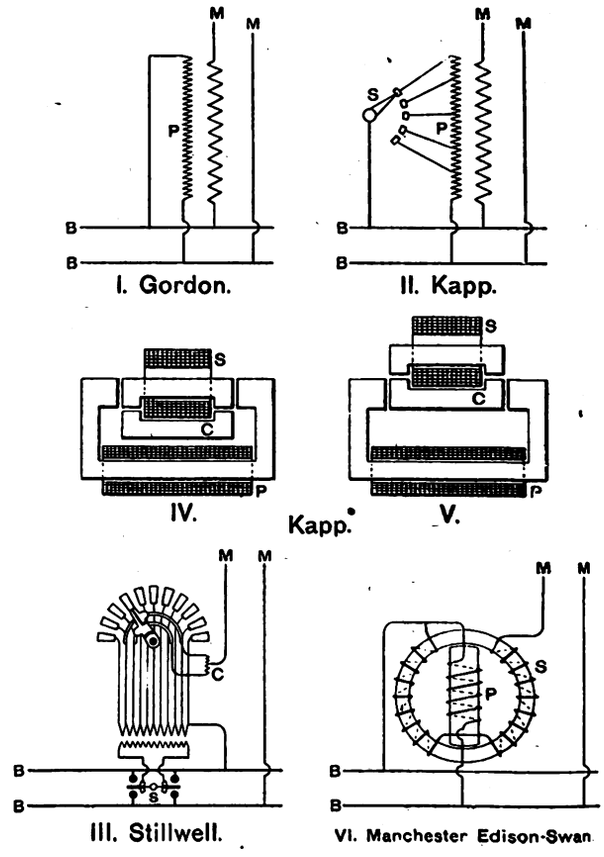

FIG. 3.

to avoid short-circuiting a coil when being moved from one segment to another, and also to get over the objection of the additions to the voltage taking place in jumps, the necessary result of using a segment switch. The principle of its action is entirely different to the others, the variation in effect being obtained by a movement of the iron core. IV. shows the apparatus in the position of maximum effect, the magnetism created by the primary coil cutting the secondary coil. In V. the core and secondary coil are removed to the position of no effect, the magnetic lines flowing along the core C, outside the secondary winding instead of through it. We are not aware that this regulator was ever made ; it is, perhaps, scarcely fair to criticise it, but it is apparent that in the position shown in V. the self-induction of the secondary would result in a serious loss of pressure in the feeder, and in the position shown in V. the magnetic leakage would be appalling.

Part VI. of Fig. 3, Fig. 4 and Fig. 4A illustrate the regulating transformer manufactured by the Manchester Edison-Swan Company (Limited), as first made for the Bolton Corporation. In this design the primary coil is wound upon a shuttle-shaped core, and the secondary winding upon a ring-shaped core. Between the positions of maximum effect and no effect the primary coil, with its core, rotates through an angle of 90deg. The action is as follows:—In the position of maximum effect the shuttle occupies a vertical

Digitized by Google

position and the magnetic flux cuts the secondary coil, which is wound in two sections, one on each side of the ring, and generates the full volts required. In the position of no effect the shuttle is horizontal, and the magnetism cuts half the secondary turns in a positive sense and half in a negative sense, the resultant effect being of course nil. Between these two positions any gradation of augmentation can be obtained. It is evident that if the shuttle be rotated beyond the position of no effect (if the transformer is being used as a feeder regulator) volts will be subtracted from, instead of added to, the feeder volts. The points to which special attention were paid in the design of this apparatus were the constancy of magnetic flux in all positions, the reduction of the iron path to the shortest possible length to avoid iron loss; and the obtaining of a mechanical and compact apparatus which would lend itself to easy and safe manipulation by the switchboard attendant.

On the table we have one of the Manchester Edison-Swan regulators at work. The Manchester supply being a continuous current—a motor-alternator first converts it into an alternating

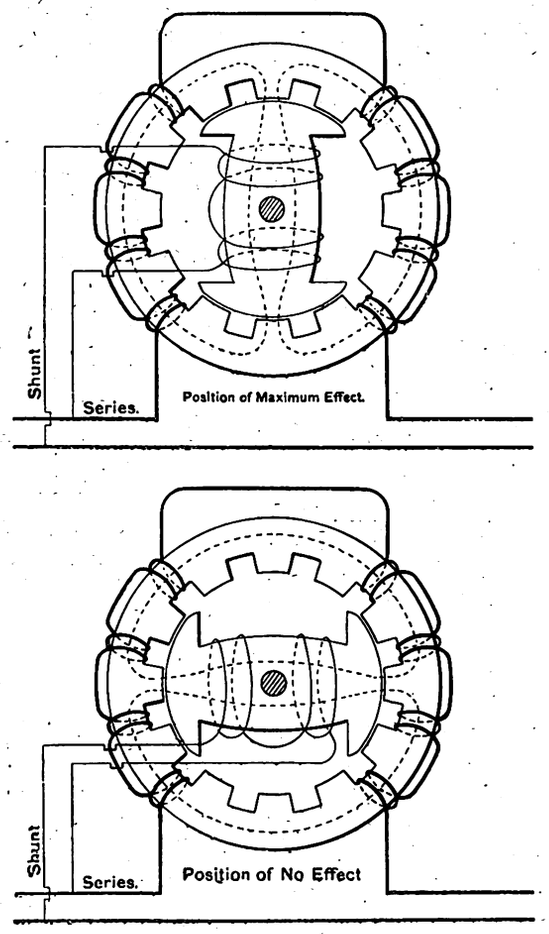

FIG. 4.

current of about 20 complete periods per second. The alternating current supplies an incandescent lamp, and the regulator is so connected that the pressure at the lamp terminals can be raised or lowered by hand adjustment of the lever on the side of the case.

Compensators.—With regard to the means of indicating the feeding point volts at the station end, there are several methods by which this can be done. Pilot wires brought back from the feeding points to the voltmeters naturally suggest themselves in the first place, but there are objections to their use, of which the principal one, perhaps, is their excessive cost, especially when they are used in connection with long feeders. A very simple method of indicating what is the required pressure at the station end of the feeders in order that the supply at the far end may be independent of variation in load, consists in marking on the feeder ammeters a second scale of numbers—let us say in red figures—these numbers to indicate the required value of the station volts for any position of the ammeter needle.

A step in advance of this, is a method which is more generally used in America than in this country. It consists in connecting the voltmeter in series with the secondaries of two transformers; a shunt transformer T_1 (A, Fig. 5) with its primary across the mains, and a series transformer T_2, of which the primary is traversed by the main current. The secondary of this transformer being closed through an adjustable resistance R, it will be readily seen that by suitably varying this resistance to suit the length and size of the feeder, the potential difference between the terminals $t\,t$ may be adjusted to any particular fraction of the volts lost in the feeder. It follows that by setting this potential difference against the potential difference at the secondary terminals of the shunt transformer, the readings on the voltmeter will be an indication of the actual pressure at the feeding point. In B on the same diagram is shown the way in which this method of "compounding" the feeder voltmeter is illustrated in Dr. J. A.

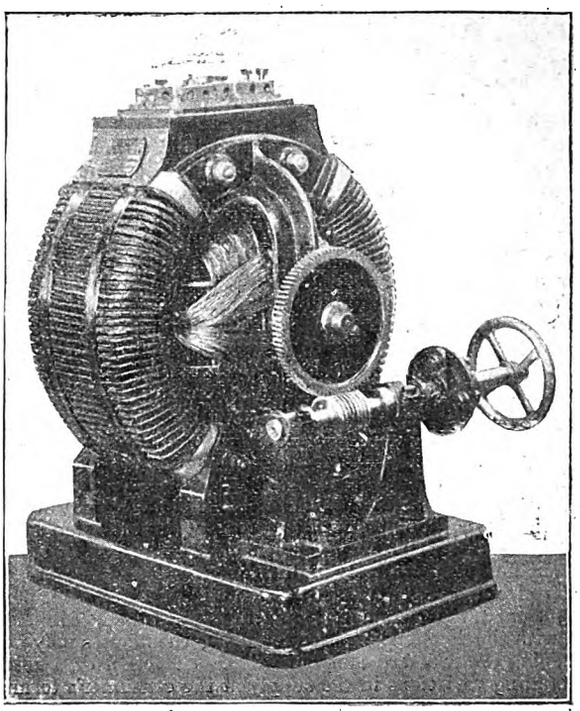

FIG 4A.

Fleming's book on transformers. In the text we read that "the electromotive forces of the two transformers are opposed to one another"; but this will not be the case unless the secondary of the series transformer is closed through a resistance, as in A. The secondary volts of the shunt transformer being in opposite phase to the primary volts, and the induced volts in the series transformer being approximately ¼ period behind the main current, these two E.M.F.'s cannot be set *against* one another, and their sum must necessarily be *greater* than the value of any one of them.

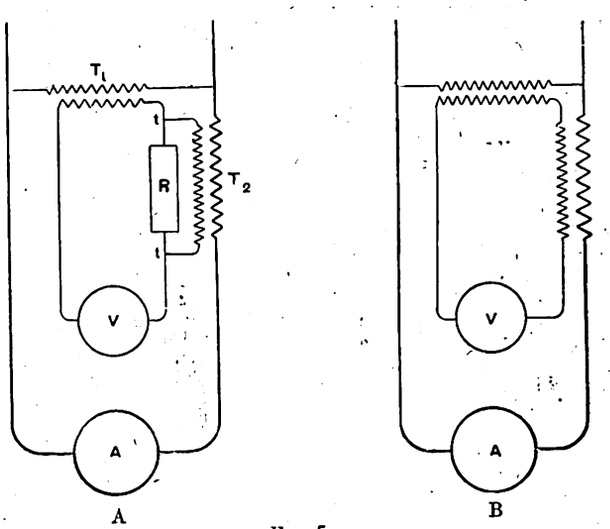

FIG. 5.

Drop in Distributors, &c.—We have so far dealt only with the loss of pressure in the feeders, and methods of keeping the volts constant at the feeding points. Beyond this the system must be self-regulating, that is to say, the loss in pressure between no load and full load must not exceed a certain definite amount. The amount of permissible variation at the consumer's terminals as fixed by the Board of Trade is 4 per cent. If, therefore, we proportion

Digitized by Google

the distributors to give a maximum drop not exceeding 2 per cent., this leaves another 2 per cent. for permissible drop in transformers. And here it may be as well to point out the disadvantage of specifying for transformers having a very small drop between no load and full load, without considering the effect of the drop upon the first cost and efficiency at light loads. It should always be borne in mind that for the same cost of material a transformer may be made to give either a small drop with a comparatively large iron loss, or a fairly considerable drop with greatly reduced open circuit losses.

As an illustration in actual practice which bears out this statement, a few months ago we tested a transformer for which the makers claimed an unusually small loss at light loads. The tests proved that the claim was undoubtedly well justified, but at what cost? The drop on volts on secondary terminals between no load and full load was no less than 5 per cent. On the other hand, a transformer of the same output by another maker had an open circuit loss nearly 1½ times as great, and this, although the weight of the transformer, and, therefore, the amount of material in it, was greater than the first one; but this greater iron loss was necessary in order to bring the drop within reasonable limits, the maximum variation being just within 2 per cent. In very small transformers it is difficult to keep the drop much below 2½ per cent.; a better regulation than this is rarely found in practice, notwithstanding specifications and makers' published figures.

With regard to the drop of pressure in the house wiring, we believe there is very little that is new to be said on the subject. It should, however, be borne in mind in calculating sizes of wires that their effective resistance to alternating currents is always a little greater than when they are traversed by a continuous current. Mr. E. Hospitalier has worked out a very convenient table, which will be found reproduced in *The Electrician* of January 12, 1894, and from which the increased resistance of wires to alternating currents for various diameters and frequencies may be easily obtained. It is, perhaps, needless to remark that this increased resistance is practically negligible except for wires, say, over ½in. in diameter, and comparatively high frequencies.

Before leaving this first section of the Paper, it should, perhaps, be mentioned that a small regulating transformer connected in series with the low-tension wires entering the houses may be used for keeping the pressure constant within a fraction of a volt, notwithstanding variations in the supply at the consumer's terminals.

Reduction of Light Load Losses.

There are few subjects of greater interest to the electrical engineer in charge of an electricity supply station than the question of light load economy. The maintenance of a continuous supply cannot be avoided, but the cost of generation during the hours of light load is enormous. The waste—and no other word adequately expresses the loss which takes place—is not only in fuel, but in wages and capital. There is no occasion to define the lightness of the load during the small hours of the morning and the long hours of daylight; in the majority of electric light stations in this country the feeder ammeter needles rest persistently at zero. It is to such stations that our remarks will apply. An examination of the question shows us that there are perhaps four ways of meeting the difficulty:—

1. Installing accumulators which are charged during the hours of heavy load and employed during the hours of light load in driving a motor alternator.
2. By running a small, and therefore more economical, light load plant.
3. By a gas engine and gas generator plant.
4. By adapting one of the smaller units in the station to work at a relatively high economy when lightly loaded.

Below we deal briefly with these four methods.

Installing Accumulators.—Mr. J. C. Howell, supported by Mr. Crompton, endeavoured some time ago to persuade the members of this Society that accumulators offered a means of saving many tons of coal per diem, even if they were only used as resistances for shunting the balance of current required to raise to full load the output of a steam dynamo. This startling assertion was accepted in many quarters, but we are unable to allow that accumulators can possess such a virtue. The question of their adaptability to alternate-current stations in conjunction with a motor alternator to effect economy becomes a difficult one to decide. The Bolton Corporation are putting this plan to a practical test, and we shall look forward to hearing at a later date some account of their experiment. It is a question of interest on capital outlay, depreciation and maintenance on the one hand, against saving in fuel and wages, and also the undoubted advantage of being able at times to shut down the steam plant entirely, on the other.

Separate Light Load Plant.—This is the plan which has found most favour up to the present time. One objection is its first cost, and another the frequent necessity for changing over from one plant to another, which, as it involves paralleling, needs the presence of a skilled attendant. This is felt most in the early morning in winter time when the load is relatively heavy for an hour or two, and a small plant cannot meet the demand.

Gas Engine and Gas Generating Plant.—At first sight a gas engine appears particularly fitted for this purpose, as it is theoretically an engine with a high efficiency at light load, on account of the gas consumed being proportional to the indicated horse-power. But there is another factor which influences the gas consumption, viz., the friction of the engine. In order to adapt a gas engine to driving an alternator it must have two or more cylinders and a heavy flywheel, the consequence being that the standing friction losses are largely increased, thus seriously affecting the economy at light loads. The first cost of such a plant is, of course, much higher than that of a steam engine of similar power.

Adapting one of the smaller Units in the Station to work at relatively High Economy when Lightly Loaded.—We are fully aware that in recommending this plan as being the most effective and economical, we are laying ourselves open to considerable criticism, especially as some of the suggestions we shall make are in the direction of rather bold departures from present practice. But it must be remembered that in dealing with the difficulties of a low "load factor" we must expect to be obliged to surrender some of our prejudices. The difficulties are peculiar, and may have to be met in a peculiar manner. It is impossible to deal with this subject without saying something about the many arrangements which tend towards economy at light load in the generation and transmission of steam. Time will not admit of the discussion of the different types of boilers. It is, of course, unwise to install a small boiler for light load, and we do not suppose that anyone would think of doing so, but it does not seem to be generally so well known that a Lancashire boiler, at any rate, works at a much higher economy at quarter load than at full load if it is well lagged and carefully stoked. A boiler cannot have too much heating surface, though it can have too much grate area. With careful stoking, a consumption of 5lbs. of fuel per square foot of grate area per hour in a Lancashire boiler will give a splendid evaporative performance of over 12lbs. of steam from and at 212°F. per pound of coal, or 10 per cent. better than with a normal consumption of 20lbs. of coal per square foot of grate per hour.

Economiser.—It might be thought that an economiser would not effect much saving at light loads on account of the lower temperature of gases; but we have obtained an augmentation of temperature of the feed of 138°F. with a 96-tube Green economiser, when working a Lancashire boiler 30ft. by 7ft. at quarter load, and burning 5lbs. of fuel per square foot of grate per hour. Prof. Kennedy has obtained an evaporation of 12·4lbs. of water per pound of fuel with economiser, and 11·7 without, when burning only 6lbs. of fuel per square foot of grate per hour.

Boiler Feed.—The wastefulness of steam feed pumps is well known, and in many stations electrically-driven pumps are now being fitted. Where the feed water is heated above 150°F. a feed pump of some sort becomes necessary; but in other cases injectors offer a means of feeding the boiler which is simple, inexpensive, and, we venture to say, economical. The three objections generally made against the use of injectors are—unreliability, small range of regulation, and lastly, that they are uneconomical. As to the first objection of unreliability, this is not borne out in practice so far as our experience goes, but a steam pump as a stand-by should undoubtedly be erected. The second objection of the small range is easily got over by fixing three or four different-sized injectors delivering in parallel into a common or "omnibus" delivery pipe. They work perfectly well in parallel, and in this way any required rate of feed can be obtained. The third objection of their being uneconomical is not, we think, a true one. Both in theory and in practice, as far as we have been able to ascertain, they are more economical than steam pumps. As a pump pure and simple the injector is, of course, very inefficient, but energy cannot be extinguished, and it therefore follows that all the units of heat in the steam supplied to the injector are returned to the boiler, with the exception of the equivalent of the work done (the product of the volume of water injected and the back pressure) and a small loss due to radiation. It must of course be remembered that though all the heat is returned to the boiler, it is returned at a lower temperature—in fact the live steam is used to heat the feed water from, say, 60°F. to 150°F., and this process violates one of the first conditions of economy. But compare it with an ordinary steam pump; about 50 per cent. of the total heat in the steam supplied to the pump is rejected in the exhaust, to which must be added large losses due to radiation, and the more obscure losses due to reciprocation. It is difficult to compare the relative efficiencies of the one method, which raises the temperature of the water from 60°F. to 1[illegible]°F. by live steam, and from 150deg. to 320deg. in the boiler; and the method in which the temperature of the feed water is raised from 60deg. to 320deg. in the boiler; but common sense seems to point to there not being much difference between the two. The use of economiser or feed water heater will, of course, somewhat alter matters, and each case should be

Digitized by Google

considered on its own merits. Our firm conclusion is that an injector is the best light load pump.

Steam Pipes.—There are grave objections to supplying the ligh load plant with steam from the main steam pipe. This plant should be erected as close as possible to the boilers, and supplied by a short auxiliary pipe of small diameter. It has been estimated that the radiated heat from every square foot of lagged steam pipe costs 300lb. of coal per annum, and Prof. Kennedy has found that the amount of condensed steam from pipes, drains, &c., amounted in one station to from 8 to 9 per cent., and in another from 5 to 6 per cent. of the total weight of feed water.

Auxiliaries—The economiser scrapers, centrifugal pump and exciting dynamo must be driven during the hours of light load; and it is evident that if these are driven separately by auxilliary engines the result will be a serious waste of steam. We prefer to arrange for their being driven by the main day load engine, using either belt, rope, or electrical transmission. As this engine is running in any case, its standing losses are not chargeable against the small extra power required, which can therefore be obtained at the very small expenditure of steam of about 12lb. per horse power.

Condensers.—We unhesitatingly recommend the ejector condenser as being the most economical light load type. No air pump is needed, and thereby a substantial standing loss avoided. It is an absolutely reliable, cheap, and efficient piece of apparatus. The type with a means of regulating the adjustment of the nozzles, is perhaps best suited to a variable load. The subject of the saving effected at light load by the removal of the standing loss of atmospheric back pressure by condensing the exhaust steam, has been so ably and fully dealt with by Mr. Willans that we do not propose to add any remarks of own, excepting to say that it is by far the most important of the means we are bringing before you for the reduction of light load losses. We show in Fig. 6 the saving of

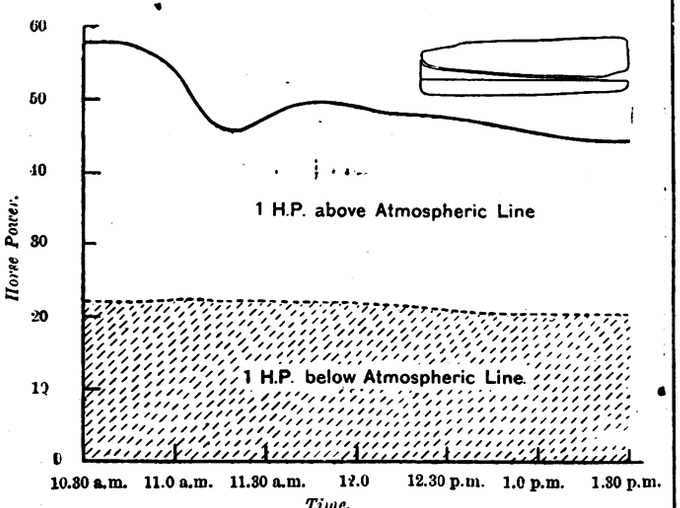

FIG. 6.

steam effected during the day time at Altrincham by the use of an ejector condenser. The diagram shows the indicated horse-power below and the indicated horse-power above the atmospheric line on the morning of December 20, 1895. The indicated horse-power below the atmospheric line amounted to about 46 per cent. of the whole, or a saving of steam consumption of about 50 per cent., against which must be set the horse-power required for centrifrugal pump, about 1 per cent. of the total horse-power of the engine.

Engine.—The discussion of the engine brings us back to our recommendation that one of the smaller units should be adapted to run economically at light load. A steam engine runs very wastefully under these conditions, partly on account of its standing losses being practically constant at all loads, and therefore bearing a larger proportion to the power developed at light load than at full load, and partly on account of the steam distribution between the high-pressure and low-pressure cylinders being unequal at light loads. The latter point should be dealt with by designing the engine with an automatic cut-off governor, which acts on both the high-pressure and the low-pressure valves. In this way a fairly equal range of temperature in the two cylinders can be maintained at all loads. The cylinders should also be steam-jacketed, on account of the range of expansion being relatively great at light loads. Of the standing losses, the back pressure of the exhaust has already been dealt with, and the loss due to radiation can only be met by careful lagging of the cylinders and their covers. Lastly, there are the important losses due to engine friction and vibration. The only way of reducing these is by lowering the engine speed. These losses are so much per revolution, and if we lower the speed we reduce them in like proportion. We recommend that the speed should be reduced by about one-third, and that the governor should be so designed as to allow of an adjustment of its springs being made by hand, in order that the engine may be under its control at this reduced speed. As far as the engine is concerned, there can be no doubt of the advantage of this plan; its effect on the electrical plant we deal with below.

Alternator.—The type of alternator which gives the highest efficiency at light load is undoubtedly the one having no iron core in its armature. But the reliability and mechanical strength of the iron-cored armature has so much to recommend it that it has found great favour, and we think rightly so, with central station engineers. Probably the protection which the self-induction of the machine affords to the whole system, in absolutely limiting the maximum current which it is possible to obtain from such an alternator to only a harmless amount above the normal, has also done its part in placing this type in the position which it occupies at the present time. Engineers will readily sacrifice some efficiency and self-regulation to obtain such a "factor of safety" as the iron-cored alternator possesses. It must be remembered, however, that the eddy current losses in an iron-cored armature are less at full load than on open circuit, a fact which was first, we believe, observed by Dr. John Hopkinson. We have recently made some experiments in connection with another matter in which this effect was very clearly marked. Apart from the windage and bearing friction, the hysteresis and eddy current losses in an iron-cored armature when lightly loaded may be considerable. On account of the peculiar raking of the magnetic lines, the iron losses in an armature, for any particular values of the induction and frequency, are greater than they would be if the same volume of iron were simply submitted to reversals of magnetism as in a transformer. The core losses in an alternator will increase approximately as the square of the induction; if therefore we could reduce the induction in the armature, a great saving of the all day losses would be effected. For instance, suppose the armature to consist (as it often does) of two separate windings connected in parallel; by switching these in series during the hours of light load the induction in the core would be halved, and the iron losses consequently reduced to one quarter of their former value; the losses in the exciting circuit being also reduced in the same proportion. Such an arrangement could not be worked without causing fluctuations in the light; but a little consideration will show that the same saving may be effected by the use of a step-up transformer. The alternator is excited to give, say, half its normal voltage, and its armature is connected in series with a transformer wound to add the remaining half of the required volts. The loss in such a transformer will be very small compared with the saving in the alternator. All that now remains to be done is to make this transformer a regulating one, which will enable the volts added to be varied without any sudden fluctuations. The change of the alternator from a small output machine to one capable of dealing with the full load it was designed for, can also be made without any variation in the light, by simultaneously reducing the volts added by the step-up transformer, and increasing the excitation of the alternator; as well as bringing up its speed, if this has been reduced as recommended when dealing with the question of engine efficiency.

The capital outlay on such an apparatus would not in any case amount to much; but where regulating transformers are used for equalising the pressure at the various feeding points, as recommended in the first part of the Paper, they can be, without any difficulty, adapted to do duty both as regulators of pressure and step-up transformers. The secondary must be wound with several separate windings which, by means of a special switch, can be connected either in series or in parallel. By means of a simple interlocking device this switch may be so arranged that it can only be thrown over at a time when the transformer is in the position of no effect.

In Fig. 7 are plotted the results of some experiments which we have made on an iron-cored alternator in order to prove what has just been said with regard to the saving of alternator losses The alternator was driven at constant speed on open circuit by means of a small continuous-current motor, and readings were taken of the power supplied to the motor for various inductions in the armature. In the diagram the vertical distances are proportional to the volts as read on an electrostatic voltmeter, and the horizontal distances are proportional to the power supplied to the motor, a correction being applied for the losses in the motor itself. The distance $O O_1$ represents the losses in windage and bearing friction; it is the power required to drive the alternator with the field-magnets unexcited. The curve $O_1 A$ is a parabola, the distance of any point on the curve from the vertical line $O_1 D$ being proportional to the square of its height above the horizontal datum line. The points enclosed by the small circles are the results of the experiments, and by their agreement with the curve $O_1 A$ serve to show that, in assuming the iron losses in the armature to be proportion to the square of the induction, the error—if any—is very small. The curves $O_1 B$ and $O_1 C$ are also parabolas, but for

Digitized by Google

equal ordinates the horizontal distances from the line $O_1 D$ are respectively four-ninths and one-ninth of their value for corresponding points on the curve $O_1 A$. These are the curves which would be obtained by connecting the secondaries of the step-up transformers in series with the armature circuit, on the assumption that the losses in the transformers themselves are negligible. In the case of curve B the alternator generates two-thirds of the full volts, and the step-up transformer supplies the remaining one-third. Two experimental readings were taken, through which the curve B_1 has been drawn. These readings, of course, include the losses in

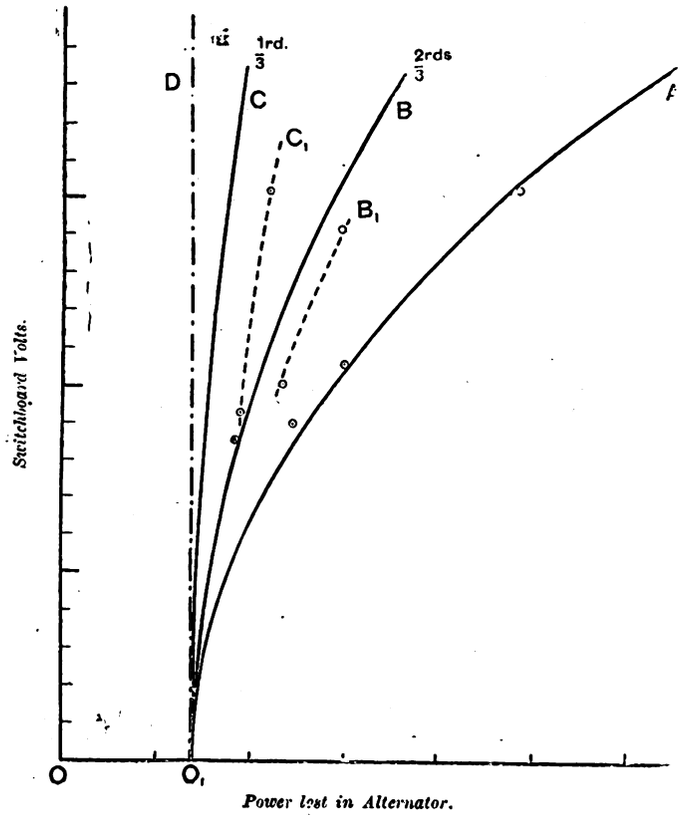

Fig. 7.

the transformer. The dotted curve C_1 was obtained when the alternator generated only one-third of the total volts. In this case, as will be seen by inspection of the diagram, the step-up transformer absorbed rather more power than in the previous experiment. Indicator diagrams of the horse-power of the engine showed the same saving.

In conclusion, we must deal with the effects of the alteration of frequency which result from the reduction of speed by one-third.

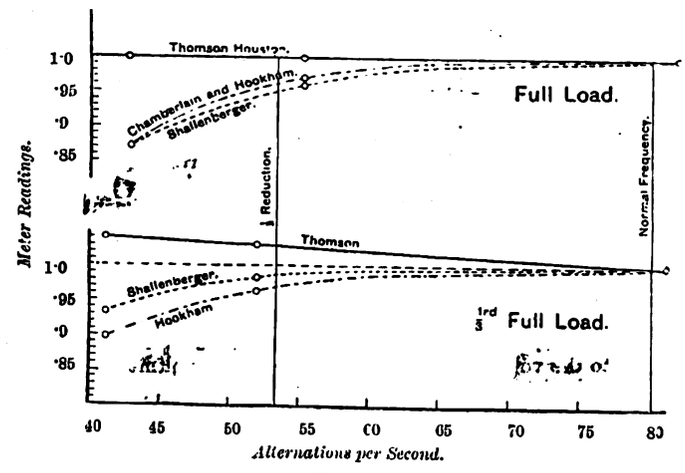

Fig. 8.

In the first place the hysteresis losses in the transformers are increased by about 25 per cent., while the eddy current losses remain approximately the same. As the C^2R losses are small when the load is light, the resulting temperature will not be abnormally high. The question therefore naturally arises as to whether the saving in the engine is not made up for by the increased losses in the transformers. The best answer to this question is to give you the result of a careful experiment made at Altrincham. In this experiment the speed of the engine was reduced from 350 to 246, and the saving in the indicated horse-power was 16·1 per cent., which is equivalent to a saving of 17 per cent. with a reduction of speed to two-thirds full speed. It must also be remembered that at Altrincham the transformers are for the most part fixed on consumer's premises, and are therefore of small size. Under ordinary circumstances with large transformers the saving should be at least 20 per cent. The effect of the alteration of frequency upon the meters is not serious. If Thomson meters are used the error for a third reduction is practically negligible. With Shallenberger and Hookham meters it amounts to from 1½ to 5 per cent. We have made experiments on these meters, the results of which are plotted in Fig. 8. In this diagram the horizontal distances represent the frequency, and the ordinates show the variations in the readings of the meters. Vertical lines are drawn at the points of normal frequency and at a third reduction. Curves are drawn for both full load and a third full load. As to the effect of the reduction of frequency upon arc lamps and alternate-current motors, there is little to be said. Our experience is that the effect upon the ordinary commercial arc lamp is not appreciable, and it will be time to consider its effect upon motors when they come into practical use. We have endeavoured in this Paper not only to make recommendations, but to support them as far as possible with figures ascertained from actual practice or experiment. We hope that some of the members present who have charge of central stations will be able to give us the result of their experience both with the difficulties of regulation of pressure and light load economy.

JACQUES' METHOD OF OBTAINING ELECTRICITY DIRECT FROM CARBON.*

The conversion of the energy of carbon directly into electrical energy, without the medium of the steam engine and dynamo, has long since become the goal for which electricians are striving. The most recent attempt at the solution of this problem is that embodied in a patent just issued to Dr. W. W. Jacques, of Newton, Mass., well known in connection with telephone work.

Dr. Jacques has discovered that if oxygen, whether pure or diluted, as in air, be caused to combine with carbon or carbonaceous materials, not directly, as in the case of combustion, but through an intervening electrolyte, the potential energy of the carbon may be converted directly into electrical energy instead of into heat.

A practical way of carrying out this method is to immerse a cylinder of carbon in molten sodium hydrate, and to force a current or blast of air into the molten sodium hydrate in such manner that it becomes impregnated with oxygen in excess over that which sodium hydrate normally contains. A circuit being completed from the sodium hydrate, which is the electrolyte, by means of a collecting electrode not chemically acted upon by the electrolyte and an extraneous conductor, to the carbon, an electric current flows continuously from the sodium hydrate through the collecting electrode and the exterior conductor to the carbon, the strength of the current depending primarily upon the rapidity with which the air is blown into the sodium hydrate, and the oxygen of the air caused to combine with the carbon.

The arrangement for carrying out the process is shown in the accompanying illustration. The carbon C is immersed in the caustic soda solution E. A pump, A, forces air into the rose R, which distributes it evenly into the electrolyte. The solution is contained in the Norway iron pot I, which forms the positive terminal, the negative B being clamped to the carbon C, which is supported by the insulating cover S. The caustic soda solution is admitted and removed by the pipes *i* and *o*. The whole is surrounded by a furnace, F, which maintains the active cell at a temperature of 400°C. to 500°C.

In this process the carbon is gradually converted into carbonic acid, which mostly bubbles up through the electrolyte and escapes. The resultant composition of the sodium hydrate remains unchanged, except as shown below, and oxygen of the air is consumed. The nitrogen with which the oxygen of the air is diluted, having no chemical affinity for any other substance present, simply bubbles through the electrolyte and escapes.

Dr. Jacques' conception of the function of the electrolyte is that it carries oxygen electrolytically from the air to the carbon, or that the phenomenon of electrolytic action causes the conversion of the potential energy of the carbon into electrical energy instead of into heat, as is the case when oxygen combines with carbon without the intervention of an electrolyte.

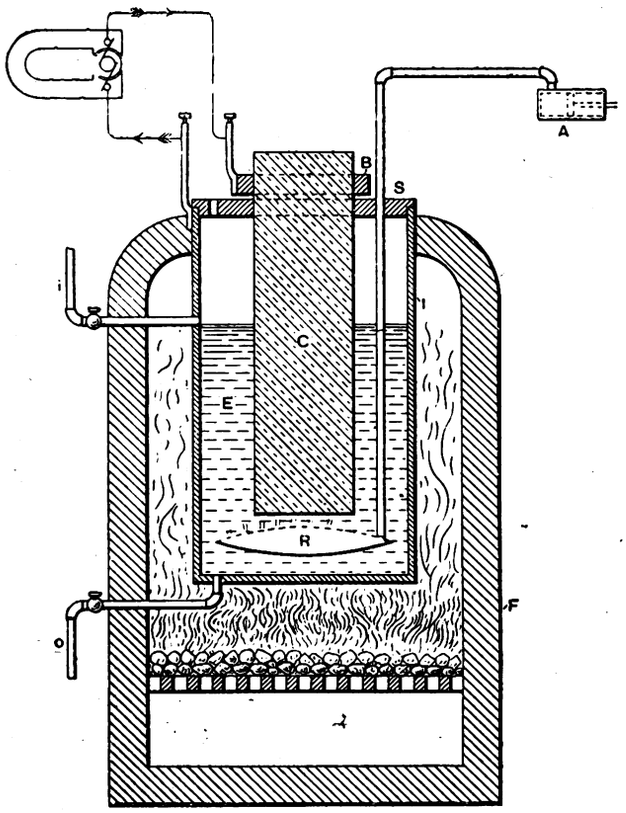
Although the greater part of the carbonic acid, whether resulting from the union of carbon and oxygen already existing in

* From the *Electrical Engineer* of New York.

Digitized by Google

the air supply, bubbles up through the electrolyte and escapes, a portion of the carbonic acid combines with a portion of the caustic soda to form carbonate of soda, and this, together with the ash from the carbon, slowly contaminates the electrolyte, and in the course of time lessens its efficiency. The efficiency may be maintained by drawing off from time to time a portion of the contaminated electrolyte and admitting a fresh portion to take its place.

The contamination of the caustic soda by its union with carbonic acid may be reduced, and its life prolonged, by adding a small percentage of oxide of magnesium. According to Dr. Jacques, the action of the oxide of magnesium is that the free carbonic acid



Jacques' Carbon Consuming Electric Generator.

combines with it in preference to the caustic soda, and that the carbonate of magnesium so formed is quickly decomposed into carbonic acid, which escapes, and oxide of magnesium, which is again ready to repeat its action. Briefly, the oxide of magnesium serves as a carrier to convey the carbonic acid through the electrolyte.

The current obtainable by this type of generator is said to be very large, but the voltage, which is not given by Dr. Jacques, is low.

INSTITUTION OF ELECTRICAL ENGINEERS.

At the ordinary general meeting held on Thursday evening, March 26th, the President, Dr. John Hopkinson, F.R.S., occupied the chair. The formal business having been transacted,

The PRESIDENT said the balance sheet had been circulated amongst the members, and he would therefore suggest that it be taken as read. He moved that the statement of accounts and balance sheet for the year ending December 31, 1895, be received and adopted. Major-General WEBBER seconded.

Mr. J. S. RAWORTH rose to propose an amendment. The President requested Mr. Raworth to be as brief as possible as there was a Paper to be read, and doubtless there were many members present who had come especially to hear that Paper.

Mr. RAWORTH: I feel that strongly. Perhaps it would suit you, sir, to postpone this discussion on the balance sheet, so that we might not suffer any inconvenience.

The PRESIDENT: We can hardly do that.

Mr. RAWORTH, continuing, said he had received from the Secretary the balance sheet which had been just described and taken as read, and as it was part of his duty to deal with balance sheets, and he was therefore to a certain extent conversant with accountants' methods, he had taken the trouble to cast his eye over this particular sheet and to endeavour to understand it. At the very outset he found some peculiarities which set him to work to get right down to the very bottom of it, because he thought if he succeeded in understanding it he might, perhaps, be able to render some service to the Institution by enabling the members also to understand it. As the result of those endeavours he thought he had succeeded in thoroughly and completely understanding it. The gist of his remarks would be, in the first place commendatory; in the second place, explanatory; and in the third place, critical. To begin with, he found the Secretary had kept the accounts of the Institution in a thoroughly accurate manner; and after he (the speaker) had constructed a balance sheet of the accounts of the Institution as it should be constructed, he found that there was not one penny of difference, but that the balance sheet came out absolutely correct. He was sure they would be very much gratified with that. Now coming to the balance sheet in detail, they would have observed one remarkable thing in connection with it, that it was the first time in their history that they had been treated to a balance sheet. They had never had one before [Sir David Salomons: Oh, yes, every year]. On every previous occasion it had been called an estimate of assets and liabilities; on this occasion it was called a balance sheet, and he ventured to suggest that there was the greatest difference in the world between these two definitions. An estimate of assets and liabilities in the view of an accountant was quite a different thing from a balance sheet. They looked upon him probably as an engineer and not as a skilled accountant, and therefore having first of all submitted this balance sheet to his friend, Mr. Hodson, accountant to the Brush Company, and next to Mr. Garcke, who stood very high in the esteem of the financial world as a skilled accountant, and got their opinion of it, he took it to a gentleman who stood, he believed, in the very first rank as an accountant in the City of London. That gentleman said, "It is not very much worse than the generality of balance sheets of these institutions. They always are lax, and I always deplore it, because in their case it is more necessary than in the case of a mercantile company that their balance sheets should be on the very best lines possible, because what is everybody's business is nobody's business, and accounts are liable to get into a very bad condition." The first thing that struck him in looking over the Institution balance sheet was a figure at the bottom right-hand corner, where they found "furniture as per last balance sheet, less depreciation, say, £14." He looked to see if that depreciation had anywhere been provided for, and found that it had not. How they could possibly, on this method of constructing a balance sheet, write off £14 of depreciation, without in some other portion of it providing for that depreciation, he did no know. Then he found, looking at the item "books, pictures, &c.," that the sum total had risen from £1,043 last year to £1,093 this year, being an accretion of £50 without any apparent expenditure on that item except the small sum of £8. 2s. for books and periodicals. He thought he had shown them sufficient to make them believe that this balance sheet had some very strange peculiarities, and the excuse he had for bringing this matter before them was that he looked on a balance sheet, an absolutely sound balance sheet, as the greatest security an institution of this kind could have for the transmission of its funds and assets unimpaired to future generations. They who were now present would soon vanish from the scene, and others would take their places. The Institution of Electrical Engineers was now constituted of themselves and some others on the list, but in a few years those names would vanish and others appear, and he thought the best legacy they could hand down to their successors was a balance sheet sound, business-like and perfect, because if they put the time off until defalcations arose, how very difficult their position would be! Instead of being an easy task, as his was that night, to show up the defects of the balance sheet, it would be a very painful operation, and one which they or their successors would think might have been tackled by their predecessors. He did not want to press this matter home that night. He did not think their Council thoroughly understood the papers they had in their hands, and if the remarks he had made had not convinced them he would proceed. The next point he had to call their attention to was a fund of which they were all very proud—he referred to the Salomons Scholarship Fund. Now, in making a fresh balance sheet out for this Institution, and coming very close on to a balance, he found he could not make the accounts balance by the sum, if he remembered rightly, of £570. 13s. 6d. He had got that amount more in assets than he ought to have, and he scanned the balance sheet from top to bottom to find out where that money had come from. If it was possible for money to get into a balance sheet without being accounted for, it was equally possible for money to get out of a balance sheet without being noticed. He found at last that they were indebted to Sir David Salomons for this £570. 13s. 6d., and he remembered that at the general meeting which took place some months ago, it had been stated that Sir David Salomons had been so good as to give them £500—he had given them, as a matter of fact, £570. 13s. 6d.—and yet they had not acknowledged that in their balance sheet in the slightest degree. Two or three years ago, when Sir David kindly gave them an addition to the fund, they put a note at the bottom, "presented by Sir David Salomons to the Salomons Scholarship Fund," and that, he thought, was a perfectly right and proper thing to put in; but on this occasion they had dropped that out and made no acknowledgment whatever to Sir David Salomons. Sir David did not confine his gift to mere pelf, he was a very rich man they knew, but he had given them more than money, he had given them his services. He had learnt from a member of the Council—he thought he should not be betraying a confidence if he stated that Mr. Dane Sinclair had told him that since he had been on the Council he had found that nobody gave more attention to the affairs of the Institution, or looked more strictly after the honour of the Institution than Sir David Salomons; and yet when they came to the balance sheet, which would be a record to future generations of how they got their money, and who were their friends in early days, there was no mention made of Sir David Salomons' gift to this Institution. From the point of view of the balance sheet it was altogether wrong for any sum to get into that balance sheet without any explanation as to how it got there. He thought he had said quite enough to show that this was not a satisfactory balance sheet for the Institution of Electrical Engineers. Now to come to another benefactor of the Institution. He did not know what his

Digitized by Google

name was, but he had given them four guineas to the library und, whatever that might be, and he found so far as he could judge from the balance sheet that they pocketed that four guineas, but had not done anything with it for the benefit of the library. They spent in 1895 £8. 2s. on books and periodicals, in 1894 £6. 19s. 8d., in 1893 £8. 18s. 7d., and in 1892 £12. 19s. 3d., so that if their good friend thought the interests of the Institution ought to be attended to in the matter of books to the extent of four guineas, he thought they might take it he had been disappointed, and they had applied that money to some other purpose. It might be said that if he did not complain why should they, but probably he was one of those individuals who would put up with a great deal rather than make any complaint whatever. There was another matter he wanted to bring before their notice, and that was that the funds of the Institution had gone up so successfully that their cash balance was £1,173. 16s. 6d., after making a provision for paying into the building fund the sum of £90 interest on their securities. He knew Sir David Salomons took great interest in this fund. He believed it was at his suggestion that it was founded, and a very good suggestion it was, and he (Mr. Raworth) thought they did owe to that fund that they should deal rightly, fairly and squarely by it. Last year they transferred the sum of £3,000 to it; this year they had transferred to it the sum of £500, making £3,500, and it had earned interest to the extent of £90, making it £3,590, but the fund only stood in the balance sheet at £3,500. He did not want to use hard words, but that poor fund had been swindled out of £90 somewhere. It seemed a nice thing to have £3,000, but if there was no interest it did not get much better. It might seem a very nice thing if he were to give them an oyster bed; but if there were a proviso that they were not to have any of the oysters it would not be of much use.

The PRESIDENT begged Mr. Raworth to shorten his remarks by dispensing with illustrations; they wanted to get along with Mr. Sinclair's Paper.

Mr. RAWORTH said that might be so. He thought it was a very important matter, but if they would allow him he would proceed at once.

The PRESIDENT: You have been already a quarter of an hour.

Mr. RAWORTH said this was the foundation of their business, so to speak, he wanted them to consider that they had a surplus this year of £1,173. 16s. 6d., and yet they had spent on premiums on Papers only the small sum of £23. 3s. This Institution was founded as they knew for the purpose of the advancement of electrical science, and by Clause V they were to make grants of money for books, apparatus, &c., for the purpose of promoting investigation; and yet having that surplus of £1,173 they had only spent £23 to stimulate their members, while the Institution of Civil Engineers had spent £412. 9s. 6d. Sometimes it was remarked that very good Papers that they might think ought to have been read before the Institution had been taken to the Civil Institution, and he thought the explanation was to be found in that particular fact. They had an enormous number of young members who had gained experience in the midst of business, which might be very valuable, and many of them would bring forward and read Papers if they could afford to do so.

The PRESIDENT: I do really think you are diverging on to matters which have nothing to do with the question.

Mr. RAWORTH said that the way in which their money was spent had a great deal to do with the question arising out of the balance sheet. However, as the President did not wish him to continue, he certainly would not. He had wished that it might not be necessary to move the resolution of which he had given notice, for he had hoped that the Council, after hearing his arguments would have come to the conclusion that this balance sheet, from which important matters were omitted, was not up to the standard to which the Institution of Electrical Engineers ought to attain, and that they would have withdrawn it. As, however, they had not done so, he had no alternative but to move "that the balance sheet be referred back to the Council for amendment."

Mr. W. M. MORDEY: I have very great pleasure in seconding the resolution.

The PRESIDENT: I will ask our accountant, Mr. Biggs, to give us the explanation of the points which Mr. Raworth has raised.

Mr. BIGGS (of Messrs. Wagstaff Blundell, Biggs and Co.) said the balance sheet as mentioned by Mr. Raworth showed the liabilities and assets in balance sheet form for the first time this year. This was decided upon in consultation with Mr. Webb and the auditors last year, and, of course, twelve months had necessarily to elapse before it could possibly be done. Having largely helped to prepare this balance sheet, he had not found much difficulty in understanding it. Gentlemen who were unacquainted with accounts might possibly find some little difficulty in understanding an ordinary balance sheet; but if they took the assets they would find on the right-hand side that the investments of the Institution were there set forward in full detail, and they amounted to £10,500. With regard to the item "furniture as per last balance sheet," he was afraid that was a slip, a mistake of the secretary or the printer, because this was the first time that the balance sheet was issued in that form. As to the £14 depreciation, Mr. Webb, in consultation with the auditors, had decided that to be quite sufficient; that reduced the furniture to £200, and Mr. Webb said there would be no necessity for any further depreciation. That represented the value of the furniture now, and would probably still represent it in 10 years time. The overdue subscriptions were estimated to realise £228. A considerable amount of care and attention had been paid to the list; it had been gone through carefully, and he was advised that £228 was a very fair figure to put it at. To the stock in hand of Institution Journals and Ronald's catalogues, the same remark applied to the books and pictures. The books in Ronald's library had been mainly acquired by gift; they were not purchased, and if any half-dozen gentlemen would like to value those books they would probably each bring out a different value. It was quite sufficient for the purposes of the Institution to put that at £1,093. Those were the assets. On the other side the different funds to which the assets belonged were set forth. There was the premium fund, the life compositions, and he might remark that with regard to the life compositions they must be shown separately under the Articles of Association, which provided that they must be so shown—the Salomons Scholarship Fund, which also was shown separately because the income was shown separately, and was applicable to a certain purpose. The Institution could not divert the assets, nor could they divert the income. The building fund and the general fund comprised together £6,700, and the distinction between the two funds was a distinction made by the Council, and for which they were solely and entirely responsible. They formed the capital account of the Institution, so that the balance sheet, boiled down, as it were, to nothing, showed that the assets of the Institution amounted to over £12,000. He did not know that he could give any other explanation. It seemed to him that, on the face of it, the balance sheet gave all the information that was necessary. Mr. Raworth, as he understood it, said it was a sound balance sheet [Mr. Raworth: No, no.]. He thought it was a very sound balance sheet himself. He thought any institution which could show £10,000 of assets which could be realised to-morrow against any liabilities to creditors of any sort whatever could not be said to be otherwise than in a flourishing condition. As regarded the donation of four guineas to the library fund, he did not know the name of the donor, nor did it form part of his business to acquire the knowledge; but the four guineas had entered into the funds of the Institution, and that for all purposes seemed to him to be sufficient. With regard to the memorandum on the balance sheet as to the donations from Sir David Salomons towards the scholarship fund, it seemed to him that the balance sheet was not the place where they should make any remarks as to the gratitude they owed to anybody with regard to any particular donation. In all probability in this case, as in most other cases, the record of the donation was entered upon the minutes, and the gratitude of the Institution was expressed there. It seemed to him that the balance sheet had nothing to do with the gratitude of the Institution towards the donor of any particular donation.

The PRESIDENT: I won't waste any more of your time, but at once put to you Mr. Raworth's amendment to my resolution.

Mr. RAWORTH: I would like to point out that the last speaker has not replied to any of my remarks with regard to the balance sheet, but has left my criticism entirely untouched.

The PRESIDENT: I will put Mr. Raworth's amendment that the balance sheet be referred back to the Council for amendment.

Twenty-seven votes were recorded for the amendment and 16 against it. The President declared the amendment carried, and immediately called upon Mr. Dane Sinclair to read his Paper on "Telephone Exchanges and their Working." At the conclusion of the reading of the Paper the meeting was adjourned until April 16th.

THE TELEGRAPH AND THE BOAT RACE.

A remarkably successful experiment has been made in connection with the transmission of the result of the Oxford and Cambridge boat race over the cables of the Eastern, Brazilian Submarine, and Western and Brazilian Telegraph Companies, and the land lines of the Pacific and European Company across the Andes. On Saturday last the lines were cleared and particulars relating to the crews and other matters concerning the race were first of all sent through, and everything made ready for the result to be dispatched to Argentina, Chili, and Peru, the precautions taken including the careful checking of the clocks *en route* by Greenwich mean time just before 12:40 p.m. when London cleared. Immediately the winning boat passed the judge at Mortlake the message was received through the Exchange Telegraph Company at the Eastern station in Old Broad-street, London, by means of the Unigraph, a useful instrument invented by Mr. T. A. Bullock and Mr. A. C. Brown. From London the message started on its way *viâ* Porthcurno (Land's End) to Carcavellos (Portugal), thence to St. Vincent, on to Pernambuco, thence to Buenos Ayres, finally reaching Valparaiso 45sec. only after the result of the race reached London. In obtaining this result, no less than nine transmissions were required. The following particulars lend additional interest to the achievement:—

As previously stated, London cleared the line at 12:40 p.m. One minute later the first message went through that Cambridge had won the toss. Subsequent messages described the state of the weather, the position of the boats before starting, the start (at two minutes past one), the relative position of the boats at various points on the river. In brief but clear terms the chances of the competitors were rapidly conveyed to the other end of the world, until finally, at 1h. 22¼min., the ninth message was dispatched that Oxford had won by a third of a length.

In order that every care should be taken to verify the accuracy of the times taken, the stations *en route* were requested to answer inquiries relative to the receipt and dispatch of the messages, and these replies show conclusively that the ninth message, which left London 1h. 22¼min., occupied only 45 seconds in transit to Valparaiso, which was thus in a position, by the aid of consecutive messages, to take a connected interest in the race from start to finish—in fact, to take a closer part in the whole proceedings than we who were within a mile or two of the race were able to do

Digitized by Google

It is needless to add that such an achievement would be impossible without preconcerted action and intelligent co-operation on the part of the intermediate stations. This co-operation was most conspicuous and laudable, each entering into the work with an earnestness which ensured success, rendering the long sections of cable and landline between London and Chili practically one length. The result of the experiment certainly reflects credit upon all concerned, and the companies over whose cables and landlines the messages passed may compliment themselves upon the activity and zeal of their staffs, and, under the conditions prevailing, the accomplishment of a feat unparalleled in the history of telegraphy.

The Direct United States Cable Company forward us the following:—"The result of the Oxford and Cambridge Boat Race was handed in at the office of the Direct Cable Company in London at 1:23½p.m., Greenwich time, and was received at their offices in New York and Boston, and in Montreal, practically at the same instant."

CORRESPONDENCE.

THE BALANCE SHEET OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is with much satisfaction that I observe that in your opinion the balance sheet of the Institution of Electrical Engineers is, or ought to be, a matter of interest to the members and associates generally.

Your leaderette of the 27th inst. on the accounts of the Institute supplies an apt illustration of one of the points which I brought up at the meeting last Thursday, viz., that no one could get a clear idea of the meaning of the balance sheet presented without very considerable trouble. I have no doubt, Sir, that you took more trouble over this matter than most ordinary members took, and that you possess for the purpose a critical mind more than ordinarily well trained; nevertheless, you have given the receipts as £4,533, which is £659 too high, against an expenditure of £2,641, leaving a balance of £1,892, whereas the balance for the year is actually £1,233. This result is, of course, a sufficient proof of our solvency, and as such I duly appreciate it.—Yours, &c., JOHN S. RAWORTH.

March 31, 1896.

[We are obliged to Mr. Raworth for calling attention to a slip in one of the five figures quoted in our Note of last week. The sum of £659 is made up of two balances on the "Receipts" side of the accounts, which should not, of course, be included in the 1895 receipts.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As I have not had any reason to look for dividends from the Institution, I fear I have been somewhat remiss in my perusal of the annual statement of accounts. Since, however, Mr. Raworth has called our attention to the subject, I have, as a matter of interest, looked over the statements of accounts for 1893, 1894 and 1895. If there is any object in issuing these accounts, I certainly think they should be submitted in a satisfactory form, although, for my own part, I am quite satisfied that the Council should keep the accounts in whatever way they think fit. I do not consider that the form of accounts as now presented can be regarded as satisfactory.

To take one item—that of "life compositions." The Articles of Association provide that "all such compositions shall be invested, and the interest alone shall be appropriated to the current expenditure." In 1893 the amount received under this head was £206, the amount invested during the year was £204. 10s., and the total investment on this account was £2,497. In 1894 the amount received was £362. 10s. and the amount invested during the year only £204. 16s. 6d., and the total amount invested £2,701. 16s. 6d., leaving a balance on the two years to be invested of £159. 3s. 6d. Now, in 1895 the amount received was £277. 10s., but as much as £552. 5s. 4d. was invested, bringing up the total amount invested to £3,254. 1s. 10d. According to this, it would appear that the sum of over £100 must have been in suspense from some period prior to 1893. I have no wish whatever to complain of this if the Council think fit to deal with the fund in this way, but it is not a satisfactory way of making up accounts that the balance of the life compositions not invested was not shown. The total amount of the life compositions is this year shown for the first time since 1893 at £3,272, of which only £3,254. 1s. 10d. is shown to be invested. Is the balance in the general fund? Would it not be more correct to show a separate account of the life compositions?

The same kind of thing appears in connection with the Salomons' Scholarship Fund. The amount received for interest in 1893 was £51. 1s. 8d., and the amount spent in awards was £70, but nothing is said of any balance on either side. In 1894 the amount received was £50. 17s. 3d., and the amount expended was £50, and the statement shows a balance of £32. 5s. 2d. How this balance is made up does not appear.

There are other items I might refer to, but I do not wish to take up too much of your space; I would, however, like to point out the extraordinary discrepancy between the statements in the annual report presented on December 12th, and the statement of accounts. In the report it is stated: "The following investments have been made during the year, viz., £554. 17s. 8d. on account of life compositions and £1,099 19s. 6d. on account of General Investment Fund." No such figures can be traced in the accounts, which show only £552. 5s. 4d. invested during the year on account of life compositions, but as much as £1,300. 12s. 8d. on account of general investment.

The report also says: "The annual accounts, when made up to the end of the year, will in all probability show a surplus equal to that of last year." Now, the surplus at the end of 1894 was £10,712. 8s. 1d. At the end of 1895, however, no surplus whatever is shown, and in place of it there is a general fund balance of £3,279. 18s. 9d., whatever that may be. The disparity between these figures arises out of the Premium Fund, the Life Compositions Fund, the Telegraphic Jubilee Fund, the Salomon's Scholarship Fund, and the Building Fund being this year regarded as liabilities, while in previous years the Council, according to the accounts, regarded these items as assets.

Now that the Council have by these accounts raised a doubt in my mind, I should certainly be very much interested to learn from someone able to enlighten us what these items really are. I have no doubt, as the Council say that the surplus this year is equal to that of last year, but it certainly is not correct to say that the accounts show it.—Yours, &c.,

1 and 2, Great Winchester-street, E.C., E. GARCKE.

March 31, 1896.

LEGAL INTELLIGENCE.

Lazare Weiller and Co. v. Bolton and Sons.

In the Appeal Court, last week, before the Master of the Rolls and Lords Justices Lopes and Rigby, the plaintiffs in this action appealed from a decision of Mr. Justice Mathew, who had decided that there had been a breach of contract on the part of the defendants, that there had also been a breach by the plaintiffs of a collateral agreement, and that the defendants were entitled to counterclaim in respect of it. Full particulars of this case were given in our issues of February 7th, 14th, and 28th.

Mr. Bigham, Q.C., Mr. J. Walton, Q.C., and Mr. Rufus Isaacs appeared in support of the appeal, and contended that there had only been one contract, and that the alleged collateral agreement was not a contract at all. On the other hand, the defendants, who were represented by Sir E. Clarke, Q.C., M.P., Mr. Lawson Walton, Q.C., and Mr. Wills, urged that the collateral agreement went to the root of the entire question, and further pleaded, by way of cross appeal, that they had been induced to enter into the original contract by misrepresentation.

In delivering judgment, the MASTER of the ROLLS said that the learned judge at the trial had, in his opinion, been quite justified in coming to the conclusion that no misrepresentation had been made by the plaintiffs, and that if any misrepresentation had been made the defendants had not relied upon it. As to the letter which the defendants contended amounted to, and which the learned judge held was, a collateral contract, in his opinion, when the terms of this letter were looked at, and when all the facts were taken into consideration, it could not be rightly said it was intended to contain a binding promise. It might be described as an agreement to enter into a further agreement, and, if so, it was not a promise which could be sued upon. Even if it were a promise, it was an independent promise, and could not be regarded as a condition precedent to the original contract. The plaintiffs were therefore entitled to succeed on all points. The appeal would therefore be allowed, and the defendants' counter appeal dismissed.

Lords Justices LOPES and RIGBY concurred.

Walter v. The Central News (Limited).

This was an action before Mr. Justice Hawkins and a special jury, brought by the proprietors of *The Times* newspaper against the Central News (Limited), in which the plaintiffs allege that the News Agency had during the late war between China and Japan supplied them with telegrams purporting to have been sent by special correspondents, but which were, it was alleged, in many cases entirely fabricated and concocted by the Central News, and in other cases were unduly altered and expanded; and further that, whereas many of these telegrams were stated to have come from persons on the spot where the events recorded had happened, they, in fact, had not come from eye witnesses. For the defence, these allegations were denied, except that if any alterations or expansion had taken place, this had only been done in accordance with the custom and practice of the news agency business. A large array of forensic talent is engaged in the case, which is still proceeding, and is creating considerable public interest, especially when the originals of the telegrams are produced and are read in conjunction with the elaborated accounts which appeared in *The Times* during the period of the war.

Sir FRANK LOCKWOOD, Q.C., M.P., for the plaintiffs, pointed out that telegraphic communication between Japan and this country was expensive, being at the rate of about 8s. a word, but if news could be sent *viâ* Shanghai the cost was only 3s. 7d. a word. During the progress of the war, and after many of the telegrams had appeared, a letter was received by the proprietors of *The Times* from a gentleman of great experience in Chinese matters throwing doubt upon the accuracy of the telegrams, and an attempt was made to obtain possession of the original despatches, but in vain, the representative of the News Agency giving the assurance that the telegrams were in almost identical terms to those received from their correspondents. It was not until May, 1895, that attention was especially called by the *Kobé Chronicle* to the matter, and in an article in that journal a long telegram appearing in *The Times* was stated to be simply an expansion of a telegram published in the *Shanghai Mercury*, where it consisted of 216 words, but in the London journals became a blown-out despatch of 665 words. This telegram was considered by *The Times* to have been a trifle too bulky, and an explanatory note was published stating that more than two-thirds of the telegram had been manufactured in London. Mr. Moore, of the defendant Company, then wrote to *The Times*, stating that the allegations of the Shanghai paper were a tissue of fabrications. Some of the telegrams read by Sir F. Lockwood, both from the original despatches and their full-bodied successors in the columns of *The Times*, were certainly marvels of creative journalism. A more serious complaint, however, was that, according to the contention of the plaintiffs, the telegram of 216 words came from Shanghai, whereas the elaborated telegram of 665 words was stated to have come from Wei-hai-wei, where the engagement described in the telegram was alleged to have taken place. This method of amplification had not been confined to one telegram, but had been systematic, and the jury would be surprised to hear that the entire number of telegrams received by the Central News Agency contained only 7,413 words, whereas there was sent to and published in *The Times* no less than 36,599, including 3,487 words, representing 17 telegrams for which the defendants appeared to have no original dispatches at all. The plaintiffs (counsel concluded) had not brought this action to recover heavy damages, but it was claimed that the money which had been paid for these fabricated telegrams ought to be refunded.

On Monday, Mr Charles Frederick Moberley Bell, assistant manager of *The Times*, was examined, cross-examined, and re-examined. The evidence was extremely interesting and instructive, especially as to the light thrown upon the methods adopted by the news agencies to render foreign telegrams "readable and complete" and suitable for up-to-date journalism. The art of amplification was not the only journalistic peculiarity which the evidence disclosed, and the readers of the daily journals will probably in future discount somewhat the large measure of praise hitherto freely bestowed upon the "enterprise" of some of our leading dailies and their "own correspondents" and "special commissioners."

Mr. Bell's examination was concluded on Tuesday, and the case adjourned to April 14th.

The Electric Installation Company (Limited) v. Lord Stratheden and Campbell.

This case came before Justices Day and Wright, being the appeal of the plantiffs from the decision of the Official Referee (Mr. Ridley), who had given judgment for the defendant both on the claim and counter-claim. The plaintiffs sought to recover £1,300 for work done in connection with the fitting up of an electric light installation at Lord Stratheden's house, known as Hartrigg, near Jedburgh. The defendant alleged that the installation was deficient, as the water-power which had been utilised was not at times sufficient to produce the necessary light, and further that he had incurred a very heavy expenditure over and above the work the plaintiffs had indicated would be necessary in order to make use of a brook of water to supply the necessary power for generating purposes. In the result it was announced that the parties had come to terms, and that the appeal would be dismissed on the defendant paying to the plaintiffs £750 without costs.

Fowler and others v. the Chelsea Electricity Supply Company (Limited) and Sandon and others v. Same.

In this case, in which, it will be remembered, the plaintiffs obtained an injunction restraining the defendants from creating a nuisance by the noise from their works, counsel for the defendants on Friday last mentioned to Mr. Justice North in the Chancery Division that his clients abandoned their application for an extension of time during which the injunction was suspended on the terms of paying the costs of the plaintiffs. The injunction therefore, takes effect accordingly.

Gulcher (New) Electric Light and Power Company (Limited) v. Murray.

In *The Electrician* for January 24th, on page 423, reference was made to an action brought by the liquidator of the Gülcher Company against a Mr. James Murray to show cause why he should not be liable to pay calls upon 300 Preference shares alleged to have been duly allotted to him in the Company. Mr. Murray's contention was that he agreed to take the shares, but only upon certain conditions, which he maintained had not been carried out.

In the previous action the Court found that Mr. Murray had no knowledge of his name being on the register of shareholders, and decided that he was not liable. Hence the present appeal.

After hearing the arguments on behalf of the liquidator, and without calling upon counsel for Mr. Murray, the appeal was dismissed with costs.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d. abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

TENDERS INVITED.—The Electric Lighting Committee of the Derby Corporation require tenders for the supply and laying of low-tension cables and junction boxes in the borough. Tenders to Mr. H. F. Gadsby, Town Clerk, at the Town Hall, not later than 12 (noon) of Monday, April 13th.

——— The Commissioners of the township of Rathmines and Rathgar, Ireland, require tenders for the electric lighting of the new Town Hall and offices, for which about 250 lights with the necessary generating plant will be required; also for an installation of telephones and electric bells. Some further particulars will be found in our advertisement columns, and tenders must be sent in to Mr. F. P. Fawcett, Town Hall, Rathmines, by 10 a.m. of Monday, the 20th inst.

——— The Edinburgh Corporation invite tenders for the wiring of the police cells for the electric light. Tenders by 10 a.m. on April 11th, to the Town Clerk, Mr. Thomas Hunter, W.S., Town Hall, Edinburgh.

——— The Willenhall District Council require tenders for the establishment of an electric call system between the fire station and 14 firemen's houses. Tenders to the Clerk, Mr. Rowland Tildesley, 65, Walsall-street, Willenhall, by 10th inst.

TENDERS ACCEPTED.—Messrs. G. Ewing Johnston and Rea, of Liverpool, have secured the contract for the installation of the electric light at the new West Kirby Hydropathic. The plant will include gas engine, a battery of accumulators, &c.

——— The Gas and Electric Lighting Sub-Committee of the Aberdeen Town Council have accepted the tender of Messrs. Crompton and Co. for a new 300 H.P. engine and dynamo for £2,600. Messrs. Siemens Bros. and Co.'s tender for additions to the switchboard at £130 was also accepted.

Digitized by Google

TENDERS ACCEPTED.—The Gas and Electric Lighting Committee of the Burnley Town Council have accepted the tender of Messrs. S. Z. de Ferranti (Limited) for the supply of 50 electricity meters at £262. 10s.

——— The Bedford Urban Sanitary Authority have accepted the tenders of Messrs. Siemens Bros. and Co. for the supply of a switchboard for £400, and of Mr. W. Bradley for the supply of 150 additional cast-iron lamp standards and fittings at £374. 5s.

——— At Tuesday's meeting of the London County Council the Fire Brigade Committee reported that the following tenders had been received for wiring and fitting up the fire brigade station in Tabernacle-street, Shoreditch, for the electric light:—

Russell and Lennard (*accepted*)	£173	15	0
A. W. Jackson	248	10	0
Pritchetts and Gold	228	0	0
Crompton and Co. (Limited)	219	0	0
Drake and Gorham	186	5	6

APPOINTMENTS VACANT.—The Council of the County Borough of West Ham invite applications for the post of electrical engineer, with a commencing salary of £300 per annum. Our advertisement columns furnish some further particulars in regard to the experience, &c., required, and applications must be sent to Mr. Fred. E. Hilleary, Town Clerk, Town Hall, West Ham, by 5 p.m. of Wednesday, April 8th.

——— An engineer and electrician is required for the Hackney public baths, salary £156 per annum. Applications to the Clerk, Mr. Geo. Grocott, Town Hall, Hackney, by noon of Thursday, the 16th inst.

LIQUIDATIONS.—At a meeting on the 21st inst. it was decided to wind up Roger Dawson (Limited) voluntarily. Mr. H. B. Johnson, 29, Gloucester-road, Regent's Park, London, N.W., has been appointed liquidator.

——— A meeting will be held on May 1st, at 27A, Sackville-street, for the purpose of receiving an account of the winding-up of the Foreign Electric Date and Time Stamp Company (Limited).

——— Notice is given of the release of the liquidator, Mr. C. J. Stewart (late senior Official Receiver), in the liquidation of Newington, Priddle and Co. (Limited).

AGENCY.—Mr. C. F. Quicke, M.I.E.E., of 72, Finsbury-pavement, E.C., has been appointed London agent to the old-established engineering firm of John Turner and Sons, of Denton, Manchester, who have recently added an electrical branch to their business.

ADDITIONAL PREMISES.—Owing to increase of business, Messrs. Ward and Goldstone, electrical engineers, of Gorton, have taken additional premises at Charles-street, C.-on-M., Manchester.

CATALOGUE.—We have received a copy of a catalogue, issued by the Campbell Gas Engine Company (Limited), describing the "Campbell" oil engine. This engine is built in sizes from 1¼ to 30 B.H.P., and is designed to work with ordinary lighting oils of from 120deg. to 150deg. flash point. The engine has been extensively used as a small motor in mills and factories and for electric lighting plants. The consumption of oil appears to be quite up to the average in economy; and from the system of governing used a high economy at reduced loads might be expected. The governor acts by missing explosions when the speed is too high. The prices of the engine are not printed in the catalogue, but may be had on application to the offices of the Company at Halifax.

THE "JANDUS" ARC LAMP.—Messrs. Drake and Gorham inform us that these lamps have been adopted by the Royal Arsenal at Woolwich and by the Army and Navy Stores, as well as by a number of electric supply companies; and that the alternating lamp, which will, we understand, contain features not to be found in other types of arc lamps, is to be ready for delivery in about a month.

NATIONAL TELEPHONE COMPANY'S SUBSCRIBERS' LIST.—It is notified by the National Telephone Company that a new and complete list of the names, professions or trades, and addresses of every subscriber to the Company's exchange system in the United Kingdom will be issued on or before July 1st next. It is important that subscribers who intend removing from their present premises before that date should communicate with the Company's manager in their district, in order that the list may be made as complete as possible by the necessary corrections being made. It will be impossible to guarantee any insertion in the list received after April 30th.

RECENT DEVELOPMENTS IN PHOTOGRAPHY.—Prof. Röntgen's recent discovery has caused a considerable demand to arise for vacuum tubes, induction coils, &c., and medical men especially will be interested to learn that the Vacuum Tube Company, of Albany-buildings, 39, Victoria-street, London, S.W., have made special arrangements for supplying these requirements. The Company owns patents in connection with the manufacture of special high-exhaustion tubes (electro-chemically exhausted) and vacuum tubes of all kinds. For the convenience of medical practitioners and others requiring to take photographs by means of X-rays, the Company have fitted up a room with a complete set of all requisite apparatus, which can be loaned at a small cost, technical advice being at the disposal of those who may require it.

THE "ENGINEERING MAGAZINE."—The contents of the April number of this excellent magazine include:—"Industrial Conditions and the Money Market," by Maurice L. Muhleman; "Railroad Corporations and Practical Politics," by Cy Warman; "Pump Irrigation on the Great Plains," by H. V. Hinckley; "Future of the Elevated Railway," by Eugene Klapp; "The Relative Value of Different Coals," by H. M. Chance; "The Present Status of Aerial Navigation," by Octave Chanute; "Modern Machine Shop Economics," by Horace L. Arnold; "Pure Water for Drinking and Cooking," by S. P. Axtell; "The Architecture of Modern Bank Buildings," by R. W. Gibson; "Determining the Value of an Iron Mine," by Nelson P. Hulst; together with the usual exhaustive Review of the World's Press. This number, as well as all the back numbers, may be obtained at the offices of the European edition, 1, 2 and 3, Salisbury-court, Fleet-street, London, E.C.

ABERDEEN.—The question of the proposed extension of the electricity supply station was considered by the Gas Committee at their last meeting, and it was decided that the electrical engineer (Mr. A. S. Blackman) should present a report on the subject. The Finance Committee were also instructed to present a report on the financial position of the electricity department.

ACQUITTAL.—At the Liverpool Assizes last week Peter Bradley, aged 26, an electrician, was charged with embezzling certain sums of money alleged to have been received by him on account of his employers, Messrs. Sharp and Kent, of Connaught-mansions, Victoria-street, London. Bradley pleaded not guilty, and the jury after hearing the evidence upheld the plea, and discharged the accused. The defence in the case was that Bradley had paid over the money or part of it, and that the balance was paid by him to Sharp and Kent's servants, whom he employed for the purpose of their business in Blackpool. Mr. McKeard, for the defence, commented on the peculiar system of book-keeping of the prosecutors' agent, and contended that the charge against Bradley, who he asserted was an honest man, arose from the lax system adopted by the prosecutors.

ASYLUM LIGHTING.—We referred in our last issue to the electric lighting of the Purdysburn Asylum at Belfast, the plant for which was installed by Mr. W. H. Drennan, of Belfast. The plant consists of two 9-kilowatt E.C.C. dynamos (90 amperes × 100 volts) coupled direct to Bumsted and Chandler high-speed engines running at 460 revolutions. The dynamos are arranged to work up to 130 volts for battery charging by varying the resistance in the shunt. A battery of 56 K17 type E.P.S. cells, having a capacity of 275 ampere hours, provides for day load and motors. Two Penman Cornish boilers are provided, and two Worthington feed pumps are arranged to feed either boiler. The main switchboard has been supplied by Messrs. Crompton and Co., and all arrangements have been made for running the plant in parallel. The washing machinery at the Asylum is worked by electric motors. The work has been carried out to the plans and specifications of the City Electrical Engineer, Mr. Victor A. H. McCowen, who acted as consulting engineer to the Board, Mr. John March acting as clerk of works.

BEDFORD.—At the last meeting of the Urban Sanitary Authority the statement of accounts of the electric light undertaking to December 31st was submitted. The capital expenditure to date amounted to £17,336. Revenue from the sale of current realised £1,114. 18s. 4d., and rental of meters £28. 0s. 6d., a total of £1,142. 18s. 10d. The up-keep, &c., amounted to £1,052. 9s. 10d., leaving a gross profit of £90. 9s. Sinking fund and interest came to £870, leaving a net deficiency of £779. 10s. Mr. Richards, in moving that the accounts be passed, said that the statement, which was the first annual one, was satisfactory. The demand for current continued to increase in a very encouraging manner. The accounts were adopted.

BELFAST.—At the last meeting of the Electric Light Committee it was stated that there had been a profit of £300 on the past year's working of the electricity supply station.——The report of the deputation recently appointed by the City Council to visit various towns where electricity was employed for traction purposes recommend the Council to adopt the overhead system of electric traction as being the most suitable for the city.

BRISTOL.—The question of electric lighting extensions was considered by the Electric Light Committee at its sitting on Saturday last, and it was decided to recommend the Town Council to borrow an additional sum of £75,000 for the purpose of extending the buildings and putting down additional plant and machinery. This report will be considered by the Council on the 14th inst. At the same sitting the Finance Sub-Committee presented the estimate of receipts and expenditure for the coming six months. It was stated that the revenue from the undertaking would be more than sufficient to defray the working expenses and to meet the interest

Digitized by Google

on loans, sinking fund charges, &c. Various applications for extensions of the mains were received, and it was decided to carry them out. At the present time there is an equivalent of 28,134 8 c.p. lamps connected, and the Committee have applications in hand for over 2,700 more.——Major-General H. S. Crozier held a Local Government Board inquiry on Friday last into the application of the Town Council for sanction to borrow £25,000 for electric lighting purposes.

CHURCH LIGHTING.—The parish church of Rottingdean, Sussex, is now lighted electrically.——St. Barnabas Church, Sheffield, is being wired for the electric light.

CALCUTTA.—The contract for lighting the Sibpur College by electricity has been placed with Messrs. Martin and Co.

CARDIFF.—Mr. G. W. Willocks, M.I.C.E., held a Local Government Board inquiry on the 26th ult. at Cardiff into the application of the Corporation for sanction to borrow a further sum of £12,500 for extensions to the electricity works. The Town Clerk explained that the sum of £45,385 had already been borrowed for electric lighting purposes, and that the present loan required was for additional engines, boilers and other plant, additions to the station, and extension of the mains. The Borough Engineer said that the demand for current had been in excess of their anticipations. At present there was an equivalent of 10,000 8 c.p. lamps connected, and applications had been received for 2,500 more, which they could not supply until they had put down additional machinery, and the proposed outlay would provide for an additional 10,000 8 c.p. lamps. There was no opposition to the application.

DARJEELING (BENGAL).—The Darjeeling Municipality have decided to install the electric light at several large buildings under their control at a cost of 95,000 rupees, the estimated annual upkeep being 9,000 rupees. They will obtain a loan from the Government for the necessary funds. The contractors for the work are Messrs. Kilburn and Co., of Calcutta.

DERBY.—Under the presidency of the new Chairman, Councillor J. P. Thompson, the Electric Lighting Committee of the Corporation last week discussed a report by the resident electrical engineer, Mr. Christie, containing statistics as to the working of the electric lighting scheme during the past four months. Subsidiary schemes which have recently been completed, relating to the electric lighting at the Guildhall and the cattle pens, have entailed an outlay of £190 and £154 respectively.

ELECTRIC TRANSMISSION OF POWER IN MINES.—Continuing the correspondence in the *Financial News* which is referred to on p. 740 of our last issue, Mr. H. K. Baynes, a Director of Messrs. Easton, Anderson and Goolden (Limited), writes as follows :—

"As the successors in business of Messrs. W. T. Goolden and Co. (the contractors for the electrical transmission plant at Moodie's Gold Mining Company), we have read with interest the letter from Mr. W. B. Esson, and cordially endorse his views as to the reliability of electricity as a motive power in mining and other districts. Having supplied electrical plants to many mines, both at home and abroad, including, in Africa alone, the Champ O'Or Deep Level Gold Mining Company, the Cassell Colliery Company, Village Main Reef Gold Mining Company, the Goldfields Deep, Metropolitan Gold Mining Company, Meyer and Charlton Gold Mining Company, Roodepoort Deep Level Gold Mining Company, May Consolidated Gold Mining Company, George Goch Gold Mining Company, Salisbury-Jubilee Joint Mill, Witwatersrand Gold Mining Company, Ferreira Gold Mining Company, Nigel Gold Mining Company, &c., all of which have given the fullest satisfaction, we feel that we are in a position to speak with authority on the subject. To supply, however, any plant, whether the motive power be electricity, steam or anything else, it is necessary to know beforehand the conditions under which it is to work and the amount of power required. Neither of these factors were known in the case of Moodie's. The calculations as to the quantity of power required were prepared at Barberton, and embodied in a specification, and the plant supplied by Messrs. Goolden and Co. was designed to produce, and, in fact (as certified by Moodie's consulting engineer), produces the quantity specified. It now turns out that these calculations were quite incorrect, and that the quantity specified is altogether insufficient for the work required. Thereupon the uninitiated hasten to fall foul of electricity as a motive power, forgetting that as they cannot expect 50 H.P. out of a 5 H.P. steam engine, so they cannot hope to extract from a dynamo or motor more current than it is constructed to supply. They should address their complaints to the gentlemen who are responsible for the miscalculations in question, and not to the contractors who supplied exactly that which they were asked to supply."

EXHIBITION.—The Leicestershire Trades and Industrial Exhibition, which was formally opened on Saturday last by Sir Thomas Wright, is lighted electrically. The electrical section is well filled with, exhibits of electric light fittings and machinery, telegraph and telephone, and electric heating and cooking apparatus being shown.

FULHAM (LONDON).—A report on the proposed electric lighting and refuse destructor scheme has been prepared for the Vestry by Mr. F. H. Medhurst.

HALIFAX.—The Finance Committee decided on Friday last to recommend the Town Council to wire the Town Hall for the electric light, at a cost of £370.

HAMPSTEAD (LONDON).—The Vestry have decided, on the recommendation of the Lighting Committee, to put down an additional 300-kilowatt dynamo at the electricity supply station. It has also been decided to lay mains in Lambolle-road, Downshire Hill and Spaniard's-road.

INFIRMARY LIGHTING.—Messrs. Drake and Gorham's Manchester house have recently completed the electrical equipment of the new infirmary at Lancaster. In addition to the electric lighting installation of about 300 lights, the firm supplied and fixed medical switchboards, telephones, electric bells, &c. The County Infirmary, Stafford, has also been fitted for the electric light.

KIDDERMINSTER AND STOURPORT ELECTRIC TRAMWAY.—The Bill authorising the construction of an electric tramway between Kidderminster and Stourport has already passed the second reading in the House of Lords, but, owing to the extensive nature of the modifications introduced in Committee, it is stated that the promoters intend to drop the measure.

LONDON CHAMBER OF COMMERCE.—At the annual meeting on Monday it was reported that at the request of the Netherlands Chamber of Commerce in London inquiries had been made in the City as to the opinions of persons likely to be interested in the establishment of a telephonic service between London and Holland. Sufficient support could not, however, be obtained.

MARITZBURG (SOUTH AFRICA).—According to the *African Review* the electric light is becoming very popular in this town, and many business and private houses, as well as the Legislative Assembly, are being wired.

MERSEY RAILWAY COMPANY.—The Birkenhead Town Council have decided to withdraw their opposition to this Company's Bill, a clause in which relates to the adoption of electricity as the motive power.

SCHOOL LIGHTING.—The new technical schools at Salford have been fitted for the electric light by Messrs. Drake and Gorham's branch at Manchester. 1,300 incandescents and a number of arc lamps and alternating motors for driving fans, &c., are included in the installation. Current is taken from the Corporation mains. The County Technical Schools at Stafford have also been fitted for the electric light by the same firm.

SOUTH AFRICA.—Those interested in South African matters will find a recent publication, the "*Argus* Annual and South African Gazetteer," a useful reference book. This is the 29th year of publication, and the work, which is published at 6s., can be obtained of the Argus Company at Johannesburg, Cape Town and Pretoria, or at the London offices, 164, Fenchurch-street, E.C. The information includes all the usual items of a year-book of this character, in addition to much other useful information not to be found in any similar publication.

LECTURES.—An interesting lecture on "Practical Electricity and Electric Lighting" was delivered on Saturday evening last at Ashton by Mr. Herbert Wooler, A.I.E.E., of the firm of Messrs. F. H. Royce and Co., Hulme.——Mr. E. Manville lectured before a crowded audience on Saturday last, at the lecture hall of the Free Library, Swansea, on "Municipal Electric Lighting and Motive Power."——Mr. Mathew Buchan lectured on "Electric Light *v.* Gas Light" at Dunfermline last week.

MILL LIGHTING.—The electric light has been introduced into the Avon Paper Mills, Linlithgow. Incandescents are employed for lighting the interior and two 1,000 c.p. arcs illuminate the approaches to the mills. The installation was carried out by Messrs. Lowdon Bros., Dundee.

NEWCASTLE.—The new telephone exchange of the National Company was formally opened on Tuesday by the Mayor, Mr. Riley Lord. Conversation was conducted between Newcastle, Leeds, and Sheffield.

NEWINGTON (LONDON).—Major Philip Cardew, R.E., held a Board of Trade inquiry on Monday last into the application of the Vestry for a Provisional Order for the parish. The London Electric Supply Corporation opposed the application on the ground that they were authorised in 1889 to supply electric current to the parish, and that they had since executed the necessary works and made arrangements for supplying the parish with electrical energy. The County of London and Brush Provincial Company and an association styling itself the "Newington and Walworth Ratepayers' Association" also objected to the granting of the Order.

NORTON.—A project is on foot for the construction of a system of electric tramways to connect this town with Stockton, Thornaby, and Middlesbrough. It is proposed to acquire the existing lines of the Imperial Tramway Company in the latter town, and the Thornaby, Stockton and Norton interests of the Darlington and Stockton Company. It is stated that the District Fund Committee of the Stockton Town Council object to the use of the over-

Digitized by Google

head system, and if that Corporation will not give its permission then the promoters intend to confine their attention to Thornaby and Middlesbrough.

SHIP LIGHTING.—The latest addition to the British Navy, the Mars," which was launched from Messrs. Laird's yard at Birkenhead on Monday, has a complete electrical installation, the lighting of the ship being effected by about 900 lights. There are six search-lights of 30,000 c.p., each of which is capable of being worked by dynamos under protection. The wiring work has been carried out by Messrs. Laird Bros.——The new Japanese battleship, the "Fuji," which was launched from the yard of the Thames Ironworks and Shipbuilding Company on Tuesday, is also lighted electrically. The vessel is to be supplied with five powerful search-lights. All the electrical apparatus and the wiring work has been supplied and executed by the electrical department of the Thames Company.

SOUTH AFRICAN EXPORTS.—Under the classification "Electrical," goods to the value of £4,202 were exported to South Africa for the week ended March 21st, made up as follows :—Cape Town £832, Algoa Bay £302, East London £2,013, Natal £170, Delagoa Bay £885. All the above are British goods.

THEATRE LIGHTING.—The Parkhurst Theatre, Holloway, London, which is to be considerably enlarged, is to be lighted electrically.

WORKS LIGHTING.—The Triumph Cycle Company, of Coventry, have decided to light the whole of their premises electrically. Current is to be taken from the Corporation mains.

——— Messrs. Oliver and Son, the contractors for the Rugby section of the Manchester, Sheffield and Lincolnshire Railway have decided to substitute the electric light for the oil lamps used at night in the cutting near Spring-hill.

YARMOUTH.—Messrs. Lacon and Co.'s new brewery stores on the North Quay are being wired for the electric light by Messrs. W. J. Crampton and Co. Arc lamps are to be employed, and current is to be taken from the Corporation mains.

CONCERTS.—The concluding concert of the season of the Electro-Harmonic Society was given on Friday last, and proved a great success.—The staff of the City of London Electric Lighting Company held their fourth annual Bohemian concert on Tuesday last at the Cannon-street Hotel, under the presidency of Mr. Frank Bailey, chief engineer to the Company. An excellent programme was furnished, and a large attendance supported the organisers of the concert.—Messrs. S. Smith and Son, of 9, Strand, London, the well known non-magnetisable watch makers, gave their eighth annual concert at the Freemason's Tavern on Saturday last, under the presidency of Mr. Samuel Smith. A programme of more than usual length was provided, in which the names of several prominent public favourites figured.—The members of the Electrical Trades' Union held a concert in the New Clerkenwell Town Hall on Saturday evening, under the auspices of the London Central Branch, at which Mr. G. W. Montague occupied the chair. A large company were agreeably entertained.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

March 16, 1896.

779. D. MCNAMARA. Dublin. An improved automatic telephone switchboard specially adapted for private installations.

5,794. P. R. DE F. D'HUMY. Liverpool. A new or improved manufacture of insulating material for underground electric wires, cables or the like.

March 17, 1896.

5,872. J. MCLAREN. Dersingham. An improved electric lift.

5,874. T. C. HEPWORTH. London. Improvements in carbon pencils for the electric arc light.

5,884. R. BRYMER. Manchester. Improvements in electrical switches.

5,948. G. J. CARSON. London. Improvements in insulating joints. (Date applied for under Patents, &c., Act, 1883, sec. 103, September 23, 1895, being date of application in United States.)*

5,951. J. DEVONSHIRE. London. Improvements in the suspension of motors for electric or other cars. (N. C. Bassett, United States.)*

5,980. A. J. BONNELIA. London. Improvements in electric switches.

March 18, 1896.

6,048. J. DEVONSHIRE. London. Improvements in controllers for electric motors. (W. B. Potter, United States.)*

6,053. THE MORRIS TUBE AMMUNITION AND SAFETY RANGE COMPANY (LIMITED), C. CUTHBERTSON and W. H. STENTIFORD, London. An improvement in electric primers for firing guns.*

6,058. G. BAMBERG. London. Improvements in moderating electric incandescent lamps and apparatus for that purpose.

6,069. W. S. RAWSON. London. Improvements in the method of electrically coating wire and apparatus therefor.

6,071. W. ROWBOTHAM. London. Improvements in primary electric batteries.

March 19, 1896.

6,113. A. G. BURRELL. Sheffield. Improved apparatus for adapting telephone line wires for fire-alarm signals and similar purposes.

6,148. H. LEA. Birmingham. Improvements in fittings for electric lighting.

March 20, 1896.

6,197. T. E. DOYLE and J. MCKENNY. Dublin. A new or improved underground system of electric traction.

6,208 A. BALLANCE and E. H. HEWSON. London. Improvements in automatic electric switches.*

6,216. C. H. PARKER and J. PULLMAN. London. Improvements in and relating to the treatment of sodium and potassium chlorides by electrolysis.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price 8d. each.

1894.

25,312. HEWITT and CASEY. Arc Lamps.

1895.

4,065. DE FERRANTI. Electric tramways and lifts.

5,137. DE FERRANTI. Electric transformers.

5,984. BENTLEY. Telephony.

6,035. ROSSITER. Electric conductors.

8,167. LABRE and COUSSINET. Electrically heated ironing, &c., appliances.

8,222. KINGSBURYS (Western Electric Co.) Telephonic systems.

8 564. DUCEUX. Electric alarms.

20,626. BRANSON. Arc lamps.

22,143. BLAKE. Culvert or duct for wires, pipes, &c.

1896.

880. EWART and VAUGHAN-SHERRIN. Electric heaters.

1,575. SIEMENS BROS. & CO., LIMITED (Siemens & Halske). Electrolytic production of zinc.

1,611. MCGEOCH. Incandescent electric lamp holders.

COMPANIES' MEETINGS AND REPORTS.

Metropolitan Electric Supply Company (Limited).

The ninth ordinary general meeting of this Company was held on Tuesday at Winchester House, Old Broad-street, under the presidency of Sir Eyre M. Shaw, K.C.B.

The SECRETARY (Mr. E. Cunliffe Owen, C.M.G.) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, before proceeding to the business which has brought us together I have to express the very sincere regret of the Board—a regret in which I am sure that all who are present will share—that in consequence of severe illness our honoured Chairman is unable to preside over this meeting. Sir John Pender has guided and superintended the operations of this Company from its commencement, and has brought to bear on it the skill and experience of a long life combined with the energy and indomitable courage specially characteristic of our countrymen, but seldom found so conspicuous or so permanently elastic as in his case. Indeed, I need not hesitate to affirm most distinctly and emphatically that the present condition of this Company—a condition which I trust before the end of this meeting you will be able to pronounce satisfactory—is in the main due to the commercial ability and indefatigable exertions of Sir John Pender. In temporarily occupying his place, as I do to-day at the desire of my colleagues, I feel more than anyone else how much we lose by Sir John Pender's absence. In bringing before you the usual motion for the adoption of the report you will, of course, expect that I should make some remarks upon the accounts for the past year. Dealing first with that portion which shows the capital receipts and expenditure, you will notice that the expenditure has been practically confined to five items, viz., buildings £5,467, machinery £5,016, mains £18,026, transformers and connections £12,884, and meters £3,038. The expenditure on buildings has almost entirely arisen from the work of extension now in course of completion at our Sardinia-street station, where provision has been or is being made for a large increase of generating plant to enable us to cope with the increasing demand for current, not only in the district in which that station is situated, but also by means of our trunk main system in any other district where the demand may exceed the local supply. There has also been construction work at our other stations, for the purpose of completing and developing them, but this has only involved a small amount of expenditure. The next item—machinery—is due to the same causes as the expenditure on buildings, and is a part of the provision which is being made for a considerable increase in

Digitized by Google

our power of supply. The expenditure on mains, transformers and meters makes, as usual, a large item, and is about £4,000 more than was spent in 1894 under the same heads. It does not seem to require explanation, as the mains have to be continually growing to meet the statutory requirements of our large districts, and the transformers and meters have to keep pace with the increase of customers. For the purpose of meeting this expenditure it has been necessary to draw on the debenture stock authorised in 1894, of which a further sum of £31,640 has been issued, making a total of £181,640 out of the authorised issue of £250,000. We have been able to issue this amount at a considerable premium, being an average, after allowing for expenses and accrued interest, of just over 16 per cent. You will remember that in 1894 we carried the premium upon the debenture stock to the depreciation fund, but acting upon the opinion of the Company's auditors it has been decided to place the amount obtained in 1895 to the credit of the capital account. But the accounts which will have most interest for you as shareholders are the revenue accounts, and the Directors are glad to record a very large increase in income. The revenue from customers has increased by no less than £21,101 against the increase in 1894 of £16,150, and this growth has come mainly from the additional customers who have been taken on during the year, and to a small extent from the fact that the weather in the Christmas quarter was duller than in the corresponding quarter of 1894, and that consequently more artificial light was required. The total cost of manufacture during the year has been £52,536, or 49½ per cent. of the income, against £42,365 or 50 per cent. in 1894. At first sight this appears to be about the same ratio, but it really represents a decided reduction, as the cost includes a sum of £4,874 for purchase of current from other companies, rendered necessary by the fire at Sardinia-street on June 24, 1895, to which I shall have to refer later on. The fire also had an effect on the item of maintenance of engines, &c., as opportunity was taken of the closing of the station to effect a complete overhauling of the boilers and furnaces, in view of the necessities which would arise in connection with the extension of plant, the whole of which repair has been borne by revenue. The maintenance of mains has cost very little during the year, a fact due not only to the high quality of our mains, but principally to what is known as the looped ring system adopted by this Company, by which the number of joints, always the weakest part of mains, is reduced to a minimum. The item of £1,273 for parliamentary charges consists of absolutely necessary expenditure incurred in the struggle which is always going on against those who would like to take advantage of our pioneer work, and enter our districts in competition with us. The result of the revenue account is that we have made a profit of £39,154 0s. 7d., which, after adding the balance from last year, and allowing for the interest on debentures and other charges, becomes a net amount of £34,082. 4s. 3d. Taking the depreciation at the sum written off in 1894, this would have given a 5 per cent. dividend, but the Board, after careful consideration, are of opinion that in view of the future of this Company a strong reserve for depreciation is of the utmost importance, and they are sure that the shareholders will agree with them that the dividend now recommended of 4 per cent. for the year is a satisfactory one, the more especially as a very small increase in the current year should place the Company for the future on a sound and strong 5 per cent. basis. The fire at our Sardinia-street works, to which reference is made in the report, was the one misfortune of an otherwise prosperous year. That its effects were no worse are due, first, to its having taken place in the middle of summer, when our loads are lightest; secondly, to the system of trunk mains which connect our various stations; and, thirdly, to the assistance so kindly and promptly rendered to us by the London and City of London companies. Within a very short time the necessary arrangements were made, and connections completed to the assisting companies, and large use was made of the supply from these companies to supplement our own. This was necessary, as, although our trunk mains worked admirably, the increasing demand in the autumn compelled us to avail ourselves of the very cordial assistance of these companies. No time was lost in pressing forward the manufacture of plant to replace the machinery destroyed in the fire, and we are now again supplying our own requirements; but the connections will remain, and I need not point out the advantage of such an arrangement, both for ourselves and from the public point of view, as an additional security for an uninterrupted supply. I think it right to inform you that, although the fire took place between 6.30 and 7 in the evening, all the theatres but one supplied from these works were lighted as usual, and the greatest credit is due to our engineering staff for the zeal and energy they displayed on this most trying occasion. I need hardly add that the most careful preparations have been taken at all our works to render impossible the recurrence of such a catastrophe. The settlements we effected with the insurance companies were perfectly satisfactory, but as at the close of the year the reinstatement works had not been fully completed, you will observe that a suspense account appears on our general balance sheet. You will be pleased to find that it has not been found necessary to allude further in the report to the vibration difficulties which gave us so much trouble and anxiety for many years past. The steps we took under our engineer's advice to remove all cause for complaint in this direction have proved completely successful. The competition with which we have for some time past been threatened in the Strand area has quite recently become practically a fact, owing to the decision of the House of Commons Committee to recommend the confirmation of the Provisional Order obtained by the Charing Cross and Strand Electricity Company. It is needless for me to say that we felt it our duty to oppose this application to the best of our abilities in both Houses, and we are still of opinion that the granting of these powers to a rival company is an injustice to us and is detrimental to the true interests of the public. I ought to remind you that this competition has always existed in the St. Martin's district, but as we both commenced operations practically at the same time we had no legitimate cause for complaint. In the present case, however, the competition comes unfairly, as we think, after we have succeeded in building up a large and important business through our unaided exertions. I need not assure you that we shall take all necessary steps to protect your interests in this district, and that if we are forced to fight we shall do so with a determination to succeed. The steady and remarkable increase in our lamp connection is extremely satisfactory. We can observe no indication whatever of any falling off in new customers, and of course this continually increasing demand implies an increase in our capital outlay. I may here mention that to encourage a larger use of current, particularly during the lighter hours of the day, and to still further increase our business, we have decided to reduce our rates of charge to those of our customers whose consumption assists our output, and who thereby enable us to reduce our working cost. The whole question of our present and future extensions has been most carefully considered, and I may tell you that our chief engineer, Mr. Frank Bailey, laid before us some months ago his estimates of our probable requirements up to the year 1900. In addition to the works necessary for this growth of custom, the estimates provide for important re-arrangements of our system of supply, which will have the effect of a very considerable saving in our cost of distribution. I allude to the formation of transformer sub-stations which the lighting density in some of our districts will shortly warrant. These estimates have been carefully examined by the Company's auditors as well as by the Directors, and the results of the increased expenditure as foreshadowed by Mr. Bailey, in whose judgment we have the greatest confidence, point to a most successful future, and to steady increase of earnings. We have not yet arrived at any definite decision as to what form the new capital will take, but you will be called together to approve our scheme when determined upon, and I need scarcely say that the shareholders' interests will be be fully considered in making the issue. He concluded by moving the adoption of the report and the payment of the dividend therein recommended.

Admiral of the Fleet Lord JOHN HAY, G.C.B., seconded the motion.

Mr. HARRISON CRIPPS said he was very pleased to see their progress, but he regarded the dividend of 4 per cent. as a poor one in view of the limited period for which they held their concessions. He found that the cost of producing electricity in the case of this company was much greater than in the case of the Westminster, the St. James's, or the City of London Companies, and that their coal bill was also far greater than that of those Companies.

Mr. GEIBEL said he thought that the loop system adopted by the Company was the cause of their excessive coal bill, and he desired to know whether the Directors contemplated altering their system so as to bring it in accordance with modern practice.

The CHAIRMAN, in reply, said the coal consumption for the year was undoubtedly large, but the difficulties with which we had to contend, owing to the fire, made it impossible for us to arrange our supply on the most economical lines. We had to give our whole attention to supplying our customers under most difficult and trying circumstances, and naturally the methods which had to be adopted on such an emergency were not of a normal character.

Mr. CRIPPS said he thought that while the fire was going on they bought their electricity.

The CHAIRMAN: This was not the case. The current was not taken from other Companies until some considerable time after the fire. The question of mains is one which, if necessary, will be answered by our engineer; but I may state in general terms that we have a system of mains which has cost us comparatively little, and our coal consumption is high, whereas other companies have paid a great deal more for their mains and their coal consumption is lighter. But the principal point in connection with Mr. Cripps' question is the area of the different districts. Some of the districts are very compact, and can be worked more economically than ours. Our district is very large indeed, and we have a great many mains running where the inhabitants have not yet drawn upon us, as I hope they will do in the next year or two. In answer to Mr. Geibel, the chairman pointed out that in his opening remarks he had referred to the estimate of their probable requirements up to 1900, and had stated that important rearrangements of their system of supply would cause a considerable saving in the cost of distribution. He trusted that that explanation was satisfactory.

Mr. GEIBEL said he had not heard the Chairman's former statement on this point, and he was much obliged for the explanation.

The CHAIRMAN then put the resolution, and it was carried unanimously.

On the motion of Admiral Sir G. H. RICHARDS, seconded by Mr. J. B. VERITY, the retiring Directors (Sir J. Pender, M.P., Admiral Lord John Hay and Mr. J. C. Parkinson) were re-elected, as were also the auditors (Messrs. Deloitte, Dever, Griffiths and Co.).

The CHAIRMAN, in acknowledging the cordial vote of thanks to the Chairman and Directors, expressed a hope that the vote applied to the staff as well. They had the greatest confidence in their Secretary and their Engineer, and the staffs under those gentlemen, to whom they owed a great debt of gratitude for their services in the past year.

The proceedings then terminated.

Willans and Robinson (Limited).

The fourth half-yearly report of the Directors of this Company, to be submitted to the general meeting to be held at the Cannon-street Hotel, London, on Wednesday next, at 3 p.m, states that the Company's business continues to develop in a thoroughly satisfactory manner. Although, for reasons explained in previous reports, new business has been little sought for, the horse-power of Willans' engines ordered in 1895 was 27,883, against 26,624 in 1894; these figures comparing with 18,950 horse-power in 1893, the last and best year of the old Company. Even more significant is the fact that in less than three months of 1896, the horse-power ordered has reached 22,200, a development which, if more or less exceptional, yet

Digitized by Google

indicates the probability of a rapid growth of business in the future. After writing off as depreciation from plant, patents, &c, the sum of £3,769. 13s. 4d., the balance to the credit of profit and loss for the half-year (including £319. 10s. 2d. brought forward) is £11,832. 14s., out of which the Directors propose that distributions be made of 6 per cent. per annum on the Preference shares, and 7 per cent. per annum (as before) on the Ordinary shares, amounting together to £7,224. 19s. 5d. £2,500 is carried to reserve, and the balance (£821. 5s. 3d.) is carried forward. The reserve fund, as the result of the first two years' working, will now reach £7,646. 9s. 11d.

The new works at Rugby are not yet in a position to assist in the production of engines, partly from the necessity which has already arisen for extending the new buildings, and for commencing others which it had been originally intended to defer, the Directors having judged it advisable to prepare for manufacturing operations at Rugby on a larger scale than was originally contemplated.

The necessary authorisation for the contemplated issue of debenture stock should now be given, and a resolution will be submitted to the meeting to that effect. In view of the remarkable expansion of the business, and of the necessity which may arise for even further extensions at Rugby, the Directors think it will be prudent to take powers to borrow up to the full limit of £112,500, but so far as they can forsee at present an actual issue of £75,000 may suffice. The mortgages upon the Thames Ditton freeholds have been paid off.

NEW COMPANIES, STATUTORY RETURNS, &c.

ALUMINIUM PRODUCTS SYNDICATE (LIMITED).—This Company has been registered with a capital of £6,000 in £1 shares, to manufacture and deal in alumina, aluminium, ferro-aluminium, brass, &c. The first Directors are R. Starke, A. C. Jeffery, and G. Mahaffy.

BRITANNIA MOTOR CARRIAGE COMPANY (LIMITED).—This company was registered on March 24th with a nominal capital of £100,000 in £1 shares, to acquire, work, develop, grant licenses in respect of and turn to account any patents, patent rights, inventions, &c., and to carry on the business of electricians, manufacturers of and dealers in motor carriages, and parts and fittings for the same, mechanical engineers, metallurgists, &c.

NEW GENERAL TRACTION COMPANY (LIMITED).—This company was registered on March 24th with a nominal capital of £170,000 divided into 10,000 £6 per cent. Preference and 24,000 Ordinary shares of £5 each, to enter into an agreement with Edwin A. King, to carry on the business of contractors for the construction and equipment of tramways and railways with electrical and other mechanical power, and to enter into, acquire and carry out contracts, concessions or other grants for making, purchasing, or working railways, tramways, telegraph and telephone lines, electric lighting, hydraulic and other works, &c. The first subscribers are :—E. A. Hopkins (1,000 shares), and A. Jones, H. Spinks, E. A. King, E. T. Church, J. Alexander, and G. A. J. Smallman (one share each).

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to March 6th has been filed. The nominal capital is £800,000, in 40,000 Preference and 40,000 Ordinary shares of £10 each. All the shares have been taken up and paid for in full.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LIMITED).—The annual return to March 9th has been filed. Out of a capital of £250,000, in £5 shares, 30,000 shares have been taken up, and the full amount thereon has been called and paid.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to March 10th has been filed. The nominal capital is £100,000, divided into 6,452 Ordinary, 550 Founders' and 2,998 Preference shares, all of £10 each. All the Ordinary and Founders' and 1,860 of the Preference have been taken up, and the full amount has been called and paid.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LTD.).—The annual return of this Company to March 17th has been filed. The whole nominal capital of £448,200, divided into 37,350 shares of £12 each, has been subscribed for, and the full amount called and paid.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31½d. per oz. (April 1st). Consols (2¾ per cent.) 109⅝—109¾ for money, 109 1/16—109 1/16 for account; 2½ per cent. 105¼—105¾ (April 1st). Stock Exchange Settling Days: Consols, May 4th; Stocks and Shares Continuation Day, April 13th; Ticket Day, April 14th; Pay Day, April 15th; Mining Share Carry-over Day, April 11th.

ALUMINIUM COMPANY (LIMITED).—This Company announce that they intend to pay off the whole of the £100,000 debentures on October 1st next.

BARCELONA TRAMWAYS COMPANY (LIMITED).—This Company invite applications for 3,000 £10 Five per Cent. Cumulative Preference shares at par. An extraordinary general meeting of the Company was held on Friday last, when the resolutions passed on the 11th inst., increasing the capital to £300,000 by the addition of 15,000 shares of £10, and making certain alterations in the articles of association, were confirmed.

BLACKMAN VENTILATING COMPANY (LIMITED).—This Company has presented a petition for confirming a special resolution reducing the capital of the Company from £75,000 to £45,000, to be heard before Mr. Justice North on May 9th.

CALCUTTA TRAMWAYS COMPANY (LIMITED).—The ordinary general meeting of this Company was held at the Cannon-street Hotel on Monday. The Chairman (Mr. E. C. Morgan) referred to the difficulty of providing sufficient working capital, and the Directors hoped the position of the Company would be improved by the introduction of electric traction on the lines, respecting which negotiations were in progress. They felt that they had not exhausted the traffic to Calcutta, but they required more horses and rolling stock. The adoption of electricity would, he thought, enable them to get rid of many of their difficulties and to greatly increase the number of their passengers.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended March 29th were £918, against £932 in the corresponding week of 1895, a decrease of £14, The total receipts for the half-year amount to £12,656, against £12,648 for the corresponding period of 1895, an increase of £8.

CORK TRAMWAYS COMPANY (LIMITED).—An extraordinary general meeting of the shareholders of this Company was held on Saturday last for the purpose of approving a draft agreement between the Company and Mr. Wm. Murphy. The Chairman (Mr. J. Dwyer, J.P.) said the object of the agreement was to transfer to the Cork Electric Tramways Company (Limited) the powers granted to them for the construction of tramways in the city of Cork. The consideration for this transfer was the payment of £1,000 to meet the expenses incurred in obtaining the Order. The agreement was approved.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company have resolved upon the payment of an interim dividend of 2s. 6d. per share, free of income tax (being at the rate of 2½ per cent. per annum) for the quarter ended March 31st, payable on and after the 24th inst.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 29th inst. amounted to £1,133. The amount for the corresponding week last year was £1,002. Increase £131.

OSWESTRY ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).—The annual meeting of the shareholders of this Company was held at Oswestry on the 20th inst. The Chairman (Mr. E. Bremner-Smith), in moving the adoption of the report and accounts, congratulated the shareholders upon their being able to show a balance of profit on what was practically only three months' working. They started with very few consumers, but there had been a very gradual, but a very steady and substantial, increase in the demand for current; and he was glad to say that so far that demand continued to grow in a very satisfactory manner. The Directors had determined to reduce the price, and personally he considered that the proper course to take, because, though the profit had been small at the present price, it was in the interest of the Company and the consumers that the price should be reduced, as he believed it would have the effect of greatly increasing and stimulating the demand. The Directors intended to put down such additional plant as would enable them to cope with any increased demand. Various applications from private houses had been received, and they had decided to extend their mains. Once private consumers had realised the many advantages of the electric light he thought there would be a considerable demand for current, and at present many of the churches and chapels of the town were considering the matter of adopting the light. The report and accounts were adopted.

ROBEY & CO. (LIMITED).—The Directors of this Company have decided to recommend the payment of a dividend of 8s. per share on both the Preference and Ordinary stock, £3,000 being placed to reserve, and £1,000 carried forward.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee has appointed April 14th for a settling day in 3,000,000 Ordinary shares (Nos. 1 to 3,000,000) of Sir W. G. Armstrong and Co. (Limited), and have ordered the said shares to be quoted in the official list.

TRAMWAYS ELECTRICAL TRACTION COMPANY (LIMITED).—The ordinary general meeting of the shareholders of this Company was held on Monday, at which the Chairman (Lord Richard H. Browne) said that those who were old shareholders in the Tramways Company of France would recollect that the Rouen Company was not in a very good financial position. The town was very hilly, and the number of horses that had to be employed was very large in proportion to the number required for tramways generally, and this caused great expense. The Rouen Company having decided to adopt electric traction, for the purpose of equipping their lines electrically they formed the Tramways Electrical Traction Company, whose articles of association, however, enabled it to do other similar work. The Company purchased all the shares and interest of the Tramways Company of France in the Rouen Company. They then entered into a contract with the French Thomson-Houston Company for the electrical equipment of the line, and the formal opening took place on the 22nd inst. with very great success. He believed they had conclusively proved the value of electric as compared with animal traction. The Directors of the Company had entered into an agreement for the disposal of all their shares and interest in the Rouen Company, and as a result of the sale there was a balance of profit which would enable them to pay the interest on the Preference shares and a dividend of £5 per share on the Ordinary shares, leaving £2,089 to be carried forward. They thought that the proposal to wind up the Company with a view to returning the whole of the paid-up capital was the best course to pursue, and a meeting to deal with this matter would be held next month. The adoption of the report and the payment of the interest and dividend mentioned was carried.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended March 27th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,338.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 934. [No. 24. Vol. XXXVI.] FRIDAY, APRIL 10, 1896. PRICE SIXPENCE.

NOTES.

THE staff of the Reichsanstalt have, with their customary good sense, taken time by the forelock, and made a practical test of the insulating and waterproofing properties of materials used in tramway road-bed construction, with the result that these properties may now be definitely considered as negligible quantities. The specific resistance of pure cement was found to be extremely low. On the addition of sand or gravel, the resistance rose, but so also did the porosity. The resistance of pure cement after a day's sojourn under water, fell, indeed, to one-third of its original value, but concrete behaved even worse; a subaqueous immersion of only two hours' duration sufficed to bring down its resistance to one-twentieth part of its initial value. Under ordinary conditions, ordinary road-bed materials may be expected to offer the magnificent resistance to earth of about half an ohm per mile of track.

So far as mere insulating and waterproofing properties are concerned, no heed being paid to cost or mechanical suitability, a complex compound consisting of 50 per cent. stone chippings, 20 per cent. gravel, 12 per cent. asphaltic-mastic, 8 per cent. pitch and 10 per cent. German tar appears to be a most excellent substance for fulfilling the Board of Trade desideratum of "separating the uninsulated return from the general mass of earth." It is, we believe, held in some quarters that it is a mistake to attempt to separate the rail-return from the general mass of the earth; doubtless this would be so were a comparatively high difference of potential such as 25 or 50 volts permitted to exist between the far and near ends of a return, but so long as the Board of Trade ideal of seven little volts is approximately lived up to no inconvenience need be apprehended.

INSTEAD of saying that his watch was ten minutes fast, Mr. MORDEY would appear to prefer to say that it was eleven hours and fifty minutes slow. At least, this would be a fair parallel to his objection to the common practice of saying that electrostatic capacity causes a *lead* of current. Mr. MORDEY would rather have it said that it causes such a very big lag that the current gets in front of the next wave behind, and appears to be in lead of it. "The capacity current lags so much behind the wave of E.M.F. producing it," he observed in the course of the admirable discussion on Messrs. COWAN and STILL's Paper, "that it is just in front of the succeeding E.M.F. wave." But this new idea of a lag produced by capacity involves us in the difficulty that to produce a genuine lag there must be an *opposing* electromotive force, whereas the electromotive force introduced into a circuit by capacity is essentially assisting the impressed electromotive force. There would be a curious discontinuity introduced, if we had to conceive that the slightest trace of capacity introduced into a non-inductive circuit would produce a lag of a whole period, whereas the slightest increment of that trace would cause only a small diminution in that enormous lag, and all the capacity it were possible to introduce would only reduce the lag to three-quarters of a period. It certainly seems more natural and logical to say that the lead of the current increases continuously from zero to a quarter of a period as the capacity is raised from zero to infinity.

IF alternate-current engineers want to run their steam engines at reduced speed on reduced loads, as proposed by Messrs. COWAN and STILL, there are two conceivable ways in which this might be done without reducing the frequency of the alternations. Variable speed gear has been suggested for this purpose, but it is an unfortunate fact that there does not exist an efficient or reliable gear of this sort, capable of taking more than a small amount of power. Another conceivable plan would be to keep the relative speed of the armature and field coils constant, while reducing the absolute speed of the armature to one-half at low load, by giving to the field coils a rotatory motion equal and opposite to that of the armature. Thus at full load the armature might run at 300 revolutions with the field at rest; while at half or lower loads the armature and field might rotate in opposite directions at 150 revolutions. The frequency would be constant. Of course the arrangement of machinery to produce this would depend on the type of plant; but where the alternator is coupled direct between two engines, one of these might be provided with reversing gear and suitable clutches for connecting or disconnecting the field or armature.

THE short abstract which we publish in another column of a Paper on "The Thermal Efficiency of Steam Engines," read by Capt. H. RIALL SANKEY before the Institution of Civil Engineers, conveys but an incomplete idea of the nature and consequences of the suggested standard of thermal efficiency for steam engines. It is not at all clear, in our opinion, that any standard is required for steam engines which cannot also be used for other heat engines; but,

Digitized by Google

passing over this point, we may observe that such a standard is supplied with theoretical completeness by the ideal engine of CLAUSIUS. With this standard, however, Capt. SANKEY does not appear to be wholly satisfied; and we are so far in agreement with him as to say that the Clausius standard represents a size of engine, relative to its power, altogether out of agreement with practice. The difficulty, once having made up one's mind to have a standard peculiar to the steam engine, is to know how to devise one which shall have a strictly scientific basis, and yet be sufficiently near to practice to be useful. Without a sound scientific basis, a standard resolves itself into an arbitrary and empirical convention, and is exposed to the risk of being rejected by scientific experimenters. On this account we are inclined to think that Capt. SANKEY's ingeniously, yet nevertheless arbitrarily, modified Clausius standard will not meet with general acceptance among steam engine theorists.

IT may not be altogether unnatural in our mechanical engineering contemporaries that they have sometimes found a difficulty in understanding why steam practice in electric supply stations should differ from that in manufactories and mills. To the mechanical engineer an electric light station is nothing else than a factory; and he often fails to see why the mill engines and Lancashire boilers which have served so well in other factories should be discarded when it is a matter of "manufacturing electricity." This view has recently been expressed by our contemporary, the *Engineer*, in a leading article which we have reprinted. In this homily electrical engineers are chided for their neglect of the experience acquired by generations of mill engineers, and for having so little to do with the Lancashire boiler. "From the first," says our contemporary, "the Lancashire boiler has been almost absent from electric light installations. It is only recently that it begins to be used in a tentative fashion by electric light engineers," and it endeavours to prove this tentativeness by a reference to Islington, where Lancashire boilers and water-tube boilers have been put in "almost side by side."

REALLY our engineering contemporary has taken a very pessimistic view of the case, and does not appear to have fully acquainted itself with the facts. In an article which we published on August 16, 1895 (Vol. XXXV., p. 514), it was shown that no less than 60·5 per cent. of the boilers in the provincial electric supply stations are of the Lancashire type, while only 22·3 per cent. belong to the water-tube type. It is only in the metropolis, with its special conditions—absent, be it noted, from ordinary mill practice—that the compact, inexplosive water-tube boiler has a prominent place. We are glad to see that the experiment of working Lancashire and water-tube boilers together is to be tried at Islington. By varying the proportion and time of their respective duties, Mr. GAY will be able to elicit useful information as to their relative suitability. But we decline to accept this station as evidence of any tentativeness in electrical engineering practice. Some of the earliest provincial supply stations were provided with none other than Lancashire boilers; and at the present time such important stations as those at Manchester, Brighton, Bristol, and Liverpool, besides a host of minor stations, are wholly dependent for steam upon this type of steam generator.

SOME interesting researches have been made recently by Dr. A. LEBRET, on that influence of a magnetic field upon the distribution of electrostatic potential in a conductor carrying a current which is generally known as the Hall phenomenon. By means of an ingenious zero or balanced method, Dr. LEBRET has eliminated many of the disturbing influences which occur when the Hall effect is measured by deflection methods, and in consequence he has succeeded in obtaining a high degree of sensitiveness and accuracy in his apparatus. Our readers will find a full account of Dr. LEBRET's method in our columns this week, together with some account of his more recent researches on the Hall phenomenon in bismuth conductors. Of particular interest is the investigation into the dissymmetry of effect of a reversal of the magnetic field, Dr. LEBRET having detected and measured such a lack of symmetry in bismuth plates of considerable thickness. This curious feature of the Hall phenomenon, first observed by NERNST and VON ETTINGSHAUSEN, apparently has been explained by means of experiments on the zero and maximum values of the dissymmetry at various angles around a circular disc-shaped conductor of bismuth. An expression for the dissymmetry as a function of the angle was deduced, and revealed that a reversal of the magnetic field caused a change of algebraic sign in but one term in the expression. Hence the dissymmetrical values.

TO determine the hysteresis loss in a sample of iron, by means of a single observation of the "throw" of a spot of light along a scale, is the task which Mr. G. F. C. SEARLE has sought to accomplish, and the partial completion of which he has described in a Paper communicated to the Cambridge Philosophical Society. A reprint of this Paper will be found in our columns this week. The determination of hysteresis by a single direct reading is no doubt of great practical value, and it has already been accomplished in the hysteresis meters of Prof. EWING and others. These have the advantage of giving a steady reading instead of a transient "throw"; and the use of a pointer is generally preferable to a spot of light in practical work, as it does not involve using lamp or darkening the room. There is ingenuity and, so far as it is safe nowadays to say so, we believe there is also distinct novelty in Mr. SEARLE's method.

Royal Society.—The first of the two annual conversaziones of the Royal Society will take place on Wednesday, May 6th.

Verband Deutscher Elektrotechniker.—The fourth annual meeting of this Society will be held at Berlin from June 17th to 21st.

Society of Arts.—Mr. James Swinburne will deliver a course of Cantor Lectures on "Applied Electro-Chemistry," on Monday evenings, April 27th, May 4th, 11th and 18th.

King's College, London.—A special course of lectures and laboratory work on alternating currents is announced to commence on the 27th inst., of which particulars can be obtained of the secretary.

Lord Kelvin's Jubilee.—Sir Douglas Galton has been appointed to act as representative of University College, London, at the celebration, next June, of the jubilee of Lord Kelvin's professoriate in the University of Glasgow.

Electric Traction in Egypt.—Good progress is being made with the construction of the electric tramways at Cairo, the concession for which is held by a Belgian Company. A good portion of the material has already arrived, and it is expected that the first section of the line will be ready for operation in July.

South-West London Polytechnic.—From the 13th inst. the well-equipped chemical and physical laboratories of this Institute will be opened to day students on each working day except Saturday. Mr. Herbert Tomlinson, B.A., F.R.S., is principal of the Institute, which is situated in Manresa-road, Chelsea, S.W.

Congress of Chambers of Commerce.—It has now been definitely arranged that the third Congress of Chambers of Commerce of the empire, which has been in course of organisation by the London Chamber of Commerce since May, 1895, shall commence its sittings on June 8th, in the hall of one of the City companies—probably that of the Grocers' Company.

Professional Advice.—"Those who undertake to interpret natural law without proper professional advice are," says a Mr. H. V. Hinckley, in the March number of the *Engineering Magazine*, "as a natural consequence, fined for contempt in Nature's court."

Wanted, an Improved Accumulator.—A gold medal is being offered by the Société Industrielle de Rouen for an improved accumulator, having advantages in respect to efficiency, &c., over existing types. Full particulars of the competition, which closes on September 30th next, may be had from the Société Industrielle de Rouen, 2, Rue Ampère et Place de la Cathedrale.

Water-power Stations in the United States.—The *Electrical World*, of New York, has recently published a table of data of no less than 124 water-power electric supply stations in the United States, a list which covers the most important installations. Some 26 of these run electric tramways or railways, and 56 of the stations are equipped with steam plant for auxiliary power.

Electric Motors in Workshops.—On page 715 of our issue of March 27th we stated that Mr. Daniel Adamson had read a Paper entitled "Electric Driving," on March 21st, before the Manchester Association of Engineers, and had referred to the use of this method of driving at Messrs. Daniel Adamson and Co.'s engineering works at Hyde. We are requested to make two corrections, and hasten to do so:—1. The Paper was read on March 14th. 2. The electric plant referred to is in use in the works of Messrs. Joseph Adamson and Co.

Germanese American.—A copy of a little work has recently come into our hands, of which the following is a reprint of the title page. We have been at some loss to understand in what language it is written, but have come to the conclusion that it is an alloy of one part of German to two parts of American:—

"More than 2,000 questions relating to steam engineering which every engineer should be able to answer; systematically arranged for the practical tradesman to facilitate him the knowledge of his need, by giving chance for selfstudy; with argued answers, and over 500 illustrations."

Another gem, a footnote, reads as follows:—"If we speak in the future of the valve weight we consider the stem included."

Interior Conduit Wiring.—An extensive installation on the Bergmann interior conduit system has been put down at the new building of the Reichsgericht, the highest court of justice in Germany, at Leipzig. The installation comprises 3,000 glow lamps, 3 electric ventilators, 8 telephones, 50 electric bells, and 8 electric clocks. There were used 2·5 miles of lead-covered cables, 18·6 miles of paper conduits, 21·8 miles of copper conductors, and 120 switch boxes. All the conduits are sunk into the walls. The installation has been working since last September to the entire satisfaction of the authorities.

The Manchester Town Council and the Three-Wire Patent.—At the last meeting of the City Council the minutes of the Gas Committee were agreed to. They included a recommendation that £1,600 be paid to the Westinghouse Company in full discharge of all claims for royalty, present and future, in connection with the three-wire and five-wire systems in use in Manchester. The opinion was expressed that the arrangement with the Company—made subject to the condition that the Corporation should not oppose the application for an extension of the life of the Company's patents—would be advantageous to the Corporation.

Personal.—The title of Assistant-Professor has been conferred on Mr. G. U. Yule, assistant to the Professor of Applied Mathematics at University College, London, and a similar title has been conferred on Mr. A. W. Porter, assistant to the Professor of Physics at the same college.——Last week Mr. G. W. Monkhouse, who is about to commence business as consulting engineer in London, was the recipient of a presentation by the staff and workmen at the Edinburgh municipal electric supply station. The presentation took the form of a Fuller's drum slide calculator and a complete set of Crosby's steam indicators.——Mr. W. Bathurst, who has held the post of assistant engineer at the Hampstead Vestry electric lighting station since the date of its opening, was on Saturday last presented with a leather writing case subscribed for by the indoor staff as a token of their esteem. The presentation was, in the absence of Mr. Cottam, made by Mr. Egerton Sayer, engineer in charge of mains. Mr. Bathurst leaves for the Cape this week. Mr. C. O. Bastian has also, we learn tendered his resignation, and will be leaving the Hampstead station shortly.

Effects of Products of Combustion in a Gas-Engine Cylinder.—At a recent meeting of the Association of Yorkshire Students of the Institution of Civil Engineers, Mr. F. Grover, of the Yorkshire College, Leeds, read a Paper on the effects of products of combustion in a gas-engine cylinder. Dealing with the present greater economy of gas engines, the lecturer said this was chiefly due to the increased compression given to the explosive mixture before ignition. It was distinctly advantageous to expel the burnt gases. To investigate the effects of the presence of these gases upon the pressure obtained, Mr. Grover had carried out a series of experiments in the engineering laboratory of the College. He ignited pure mixtures of gas and air in the proportion of from 1 to 16 volumes up to 1 to 6 volumes, and to each pure mixture 5 per cent. (by volume) of products of combustion were added. The pressures obtained after the addition of each 5 per cent. were recorded by means of a Crosby indicator. Proceeding in this way, burnt gases were added by increments of 5 per cent. by volume until the mixture became inexplosive. The general conclusions deduced from these experiments were as follows:—(1) That the highest pressures are obtained when the volume of air present is only slightly in excess of the volume required for complete combustion; (2) that in some mixtures higher pressures are recorded when residual gases take the place of an excess of air; (3) that when the volume of products of combustion does not exceed 58 per cent. of the mixture, it is explosive, provided the volume of air is not less than 5·5 times the volume of coal gas; (4) that the time of an explosion is much reduced when excess of air is replaced by products of combustion.

Expiring Patents.—On Monday next, the 13th inst., will expire patent No. 1,769 of 1882, granted to M. Camille A. Faure, of Paris, for "IMPROVEMENTS IN SECONDARY BATTERIES." The invention relates to the manufacture of containing vessels "in such a manner that they are permanent, cheap and not easily breakable." The invention also relates to a method of suspending the "leaden sheets or electrodes" in the containing vessel. Each plate is provided with a strip of metal projecting upwards, and flat iron bars are laid across the vessel, the strips being folded over the bars, forming hooks, and secured in suitable manner.——On Friday next, the 17th inst., will expire patent No. 1,830 of 1882, granted to the late Prof. Fleeming Jenkin for "IMPROVEMENTS IN MECHANISM USED FOR

Digitized by Google

TRANSPORTING GOODS AND PASSENGERS BY THE AID OF ELECTRICITY." The invention relates to a system of electric traction commonly known as "telpherage." The claims are as follows: "First, my system of telpherage, in which a single conductor divided into sections and with connections controlled by the passing trains drives a series of vehicles or of trains by electromotors upon them which are electrically connected in series through the conductor. Second, my system of telpherage, in which two conductors divided into sections, and with connections from one to the other controlled by the passing trains, drive a series of vehicles or of trains by electromotors upon them, which are electrically connected in series through the conductors. Third, the use in telpherage of insulated wires or ropes to sustain the vehicles, and simultaneously convey the electric current to electric motors upon the vehicles. Fourth, the use in telpherage of governing apparatus upon the vehicles, which cuts out the electromotor when a certain speed is reached, and at a higher speed applies a brake. Fifth, my system of electrical propulsion, in which the electromotors of the several trains or vehicle upon the line are caused to receive the current in series, each spanning a gap in an otherwise continuous conductor. Sixth, my system of automatically blocking trains or vehicles electrically propelled in series by maintaining continuity in that part of the conductor in which a gap is required to render the current effective in propelling the train or vehicle. Seventh, my combination of apparatus for propelling trains and vehicles in series by electricity, consisting in apparatus at a station maintaining a uniform current, a conducting system by which the said current passes to and through the trains or vehicles upon the line, in series, and governing apparatus upon each train or vehicle regulating according to speed the quantity of current taken from the conductor and passed through the propelling electromotor."

Röntgeniana.—The *Comptes Rendus* for March 30th contains numerous communications on the subject of X-rays, many of which are of unusual interest. MM. L. BENOIST and D. HURMUZESCU, in spite of repeated experiments, can find no trace of electrification by X-rays, but have alighted on a phenomenon analogous to that discovered by Prof. G. M. Minchin (see *The Electrician*, March 27th, p. 736). They find that the time taken for a given fall of potential to occur is different for different bodies. If we take the time for Pt as unity, then we have the following figures:—Zn (amalgamated), 0·96; Fe-Ni, 1·38; Zn and Ag (foil), 1·41; Cu (red), 1·48; Ag (sheet), 1·53; Al (beaten), 1·92; Al (sheet), 2·12; lampblack, 1·97. "Hence the aptitude with which the different metals utilise the energy of the X-rays to dissipate electricity clearly varies inversely as their transparency for these rays." The authors suggest the use of platinum salts for photographic purposes. The "conducting-dielectric" theory of Prof. J. J. Thomson does not explain the phenomenon, and experiments made with a view of discovering a similar property in dielectrics have so far yielded negative results.——M. G. SAGNAC has a long Paper entitled "On the Diffraction and Polarisation of Röntgen Rays"; he finds that the X-rays he experimented with "do not possess wave-lengths greater than four-hundredths of a micron," and can discover no signs of diffraction or polarisation.——M. CHARLES HENRY tries his hand at co-ordinating the various results attained up to date; the following is a summary of this paper: X-rays it is almost certain are transversely-vibrating ultra-violet rays. It is true they do present interference phenomena, but according to the Fresnel-Kirchoff theory this is exactly what should occur when λ approximates zero. They are not refracted; but then Wüllner has suggested a dispersion formula in which the refractive index is a function of the wave-length, hence $n=1$ when $\lambda=0$. X-rays give rise to phosphorescence; now according to Stokes' old law, phosphorescence is due to the absorption of short waves and their transformation into longer waves; hence X-rays are ultra-violet waves, a belief confirmed by their electro-discharging powers. M. Henry further gives cogent reasons for believing that cathode rays are merely X-rays complicated by material convection, that cathode-rays become converted into X-rays on entering dense media and *vice versâ*, that all sources of light emit X-rays, though feebly as compared to Crookes' tubes. Phosphorescent bodies excited by the solar radiation emit rays which will, as has been shown, traverse optically opaque bodies, but which, on the other hand, are refracted (*vide* M. Henri Becquerel), as they ought to be, λ in this case, differing as they do sensibly from zero. Phosphorescent bodies exposed to electrical radiation emit Röntgen rays, *i.e.*, waves of much shorter wave-length which traverse optically opaque bodies, but are *not* refracted. *Voilà tout!*—We have received a collection of very excellent X-ray "graphs," the results of experiments at University College, Nottingham. The "graphs" were taken by Mr. A. H. Simpson, and are published by the Electric Photo-Printing Company, Short Hill, Nottingham.

The Ford-Washburn Storage Cell.—On page 216 of our issue of December 13th last we made a few remarks on the storage-battery-traction trials initiated by the New York and Harlem Railway Company, in the course of which we said that the "electrical industry has yet to produce a battery commercially adapted to the conditions of traffic on common roads and tramways." With this dictum the Ohio Storage Battery Company of Cleveland (U.S.A.), manufacturers of the Ford-Washburn cell, join issue. We have great pleasure in giving their side of the question as fully as our space permits. In a letter dated April, 1894, the President of the Cleveland and Berea Street Railway Company writes as follows to Capt. G. A. Ford:—

DEAR SIR: In relation to the storage battery car used upon our Cleveland and Berea line, will say the car came on our road in September, having made a number of trips on the city roads before coming, and started making six trips per day between Cleveland and Berea from October 1st to February, and making a total of about 6,000 miles, and carried about 12,000 passengers. On special occasions the motor car successfully pulled a trailer, there being upwards of 150 passengers on board the train on one trip counted. Our facilities for charging the batteries were insufficient and of a temporary order. We had no facilities for inspecting the cells, and during the entire time they were used but one set was in service, consequently making it impossible to withdraw one set from the car for charging and inspection while another was in service. One feature of the service was the placing of the car and its cells entirely in our hands for housing the car, &c., without restriction or rigid continuous inspection of our actions and treatment of the equipment, while under our care overnight and between trips, by yourself or engineer; in consequence we can unqualifiedly say the equipment of cells in the car when its service was discontinued was the same as when the initial trip was made. The reason we were obliged to surrender the use of the car and the further entire equipment of our line with your system, was due to the fact that your system in the opinion of bond-purchasing investors was not wholly removed from its formative business stages; on account of this condition existing we were deprived of the possibility of placing in service an ideal system for electric suburban traction, and you as well were deprived of the opportunity of showing in long continued use of several equipments the entire practicability of your system. The cells in the car were sold to Prof. Langley for the use of Case School of Applied Science and Adelbert College. We learn they have been found, after careful inspection, to be in as good order electrically as when first used, which certainly speaks volumes for the practicability and indestructibility of your cells, since the same cells were subjected to hard usage in service on our road.

In addition to this testimonial we have before us a long report by Profs. J. W. Langley and C. F. Mabery, of the Case School of Applied Science. The Ford-Washburn cell, we may say, has "a flat bar of lead for the positive pole, placed within a perforated conductor of sheet lead which is filled with lead dioxide. This lead conductor is placed within a porous earthenware cell. . . . The space between the internal lead conductor and the porous cell is filled with lead dioxide. This earthenware cell is placed within another perforated sheet lead conductor, and the space between the outside surface of the earthenware cell and the external lead conductor is filled with litharge. These two lead conductors, with the porous earthenware cell, constitute a single element." The cells were tested in a thoroughly practical manner over a period of two months, one test consisting in subjecting a cell to 9,000,000 jogs spread over 422 hours, during which time it was charged, discharged, short-circuited, and allowed to remain on open circuit. Generally speaking, it was shown that the internal resistance remained remarkably constant, that "sulphating" was almost entirely absent, notwithstanding the severe conditions imposed, that the plates and porous pot were in no way deteriorated, and that the ampere-hour efficiency varied from 73 to 86 per cent, and the watt efficiency from 55 to 72 per cent. We sincerely trust that the future performances of the Ford-Washburn cell wil enable us to withdraw the statement objected to.

FURTHER PROGRESS IN RADIOGRAPHY.

BY PROF. OLIVER LODGE, F.R.S.

The applications to surgery and anatomy are growing so important and interesting that they have some tendency to delay progress in the direction of a better understanding of the physical nature of the Röntgen rays. The focus-tubes now in the market are able to stand as much power as can be applied to them by an induction coil with make-and-break. Alternating currents as exciter are unsuitable; a quick sharp break is much the best. Leyden jars are quite unnecessary. A low-resistance primary, excited by two or by three storage cells and a break under alcohol, acting on a large secondary coil, are the means which I have found best for exciting the tubes. A well-exhausted tube can stand for hours discharges which are on the verge of leaping across its terminals outside the glass, and can keep quite cool all the time, although the primary contact-breaker may get partly melted. The vacuum improves in action and ultimately gets too good, so that the discharge occurs altogether outside the bulb. In that case the flame of a Bunsen suffices to liberate condensed gases from the glass and give the bulb a new period of activity. Rays so obtained are very penetrating, and make such bodies as potassium-platino-cyanide and calcium-tungstate fluoresce powerfully. These two substances are the best I have yet seen, and the second is much the cheaper, even if the former is the better, as I incline to think it is. Neither should be powdered, but should be thrown down in minute crystals, and these, when dry, should be spread on a layer of clear varnish painted over either tracing-cloth or glass. Several such layers of crystals superposed give a good screen, which, mounted as the base of a box with two eyeholes at the distance of distinct vision in dim light, enables the effect of even feeble Röntgen rays to be readily seen. Of course actual light is to be excluded by two or three thicknesses of photographic black paper or otherwise. Armed with such a spy tube, and having accustomed the eye to a dark room for some time, the screen can be seen to fluoresce under the action of rays which have penetrated considerably more than a foot thickness of solid pitch-pine. The rays which have penetrated a person's chest also have the power of exciting vivid fluorescence. Indeed, under favourable conditions, the rays which have been through one person can be sent through another, and their effect can still be seen after that. Of course clothes make no practical difference. It is rather less easy to see through a head than through a chest, but it is quite easy enough to see through every part of the body when things are working well, but in no case have I as yet been able satisfactorily to perceive any detail by this method of viewing. Whether it be merely that the light is too dim for discrimination, though apparently rather bright, or whether it be that these very penetrating rays make less distinction than ordinary rays between bone and other less dense material, I am not sure. Possibly there is truth in both these obvious suggestions. It would not be easy to read a page no more strongly illuminated than is the fluorescent screen after the rays exciting it have penetrated the trunk, and perhaps the absence of detail is thus sufficiently explained; but I have been several times forced to surmise that just as the original Lenard rays are easily stopped by a few inches of air and have feeble penetrating power, so Röntgen rays may be of two or more kinds, perhaps differing in something of the fashion that violet light differs from red; and that, whereas close to the source we get Röntgen and Lenard rays mixed, and a little further off Röntgen rays only, *i.e.*, those which discriminate most clearly and throw therefore the most instructive shadows, so after great obstruction, like a human body, only the most penetrating quality of ray gets through. And under these circumstances the interposition of the palm of one's hand scarcely adds to the shadow, nor do the bones of the palm make their appearance in so prominent a manner as one might expect from the general brightness. Against this, however, is to be recorded the fact that I have taken a photograph of a spine to discover the nature of the damage to a vertebra in a patient, and the details of the processes of the vertebræ come out well. Also I have taken a hand with rays which have come through 6in. of pitch-pine, and the bones, though a little blurred, are not bad.

Naturally the body radiographs are not easy to read, except by a skilled anatomist after some practice, because the aspect of bones which are semi-transparent, and are all projected together upon a flat surface, is by no means a usual aspect, indeed is a quite novel one, and requires to be learnt. A study of the skeleton, and some skill in drawing, is necessary in order to disentangle the superposed impressions. But the impressions themselves are not indistinct. The internal organs also appear. Comparing this method of investigation with the stethoscopic method it cannot be thought that the stethoscope is the easier. To a novice both would seem equally puzzling, and both require skill and experience.

Foreign metallic bodies in the trunk, such as a Murphy button used by surgeons for joining cut intestines, are, of course, easily radiographed. The other day I got a good impression of one of these in an adult, with only ten minutes' exposure of the plate.

But here again some evidence of possible physical interest occurs. The outline of the button, naturally at some distance from the flat, is not sharp. Its shape is quite visible, but its outline is blurred. Of course it is enlarged by the cone of rays, and its position between plate and source could be estimated exactly by its size, if only its outline were sharp. Possibly the blurring is only due to internal movements in the body, the intestines are known to be very movable; but if, as Lenard said, opacity is the nature of turbidity, the whole body glowing as it were like faintly ground glass under the action of the rays, which is just what it looks like through the described spy-tube, then this slight haziness of outline may be considered as physically explained.

A coin laid upon each plate serves as a handy label and a guide in developing. It may be worth remarking that a threepenny bit placed on top of a shilling comes out readily on a plate, and that one can "see" through several thicknesses of sheet iron such as tinplate.

As to the photographic plates used, I have found that only plates by the best makers are of any use. A cheap packet, in which some of the plates may have been already partially fogged, is utterly unsatisfactory. Hitherto Edwards' isochromatic plates have done best for me, though Marion's rapid, and probably any thoroughly good maker's, are equally good; and I do not now fancy that the isochromatic property is an essential help. Either the hydroquinone or the pyrogallate developers are perfectly satisfactory, but my assistant usually prefers the hydroquinone. In developing the plates it must be remembered that the penetrating power of the rays has enabled them to operate equally right through the film, and not chiefly on the surface; hence development may be safely pushed pretty far. This fact may have given rise to the opinion that the films are acted on from the glass outwards, instead of from the surface of the film inwards, as in the case of light. At present I am not by any means convinced of the truth of this opinion.

It would, however, be very remarkable if that interesting experiment of Prof. J. J. Thomson's should be confirmed—viz., that the cathode rays themselves inside a vacuum had no power of exciting a photographic plate. From their violent action on glass it would seem more likely that their action, though admittedly indirect, must nevertheless be strong, perhaps strong enough to undo and mask their initial effect. At any rate the experiment needs repeating.

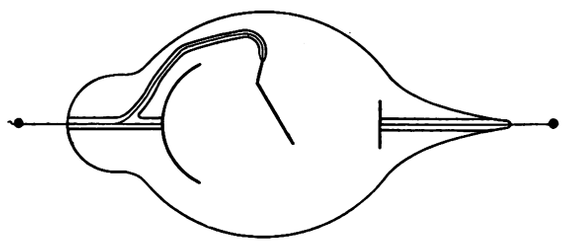
As to the source of the rays, I, like others, have made many experiments, and the results are definite enough. When the rays from the cathode, inside the vacuum, impinge first on a glass surface, then that surface is the source. It is not as if the cathode rays penetrated the glass and proceeded on their path; it is not as if the glass surface were a wave front, from every point of which a ray proceeded normally; the glass radiates X-rays just as a red hot surface radiates light. From every point a cone of rays starts in all directions, and there is no mutual interference in the lateral directions, as there would be between a number of similar sources all in the same phase. Every point of the glass radiates independently,—like a hot

Digitized by Google

surface, in fact. The best experiments of this kind were those in which I used a magnet to deflect the cathode rays on to any chosen spot or patch of the glass, and then took shadow photographs through slits and holes placed at a measured distance. The shadows of wires at a distance from the plates, taken through a narrow slit at some distance from the wire, show that if the X-radiation consists of waves at all those waves must be very small. There has been nothing, as yet, to discriminate between longitudinal and transverse oscillations. Transverse must be considered as the most probable at present; but then it is not certain that they are waves at all. If waves they must be very small ones; and the question whether they are transverse or longitudinal is almost a minor consideration if it should turn out that the wave-length is comparable to the size of molecules. The interest and importance of such an instrument of investigation as radiation with that size of wave, whereby indirectly molecules themselves would hereafter be rendered diffractionally visible, are immense.

When the cathode rays do not first strike the glass, but first strike a piece of metal enclosed in the bulb, then its behaviour depends largely on what it is connected to. My experiments on this point are not complete, but this much is certain, that if the bombarded piece of metal is attached to the cathode, so that it is unable to receive any electrical charges from the cathode stream, then it either declines to act as a source of rays at all, or else emits a radiation of the most feeble kind, which can without difficulty be attributed to a secondary cause. But on the other hand, if the bombarded disc be connected to the anode, so as to be able to receive the negative charges of the cathode stream, then it acts as a most vigorous source. In a low state of vacuum it will indeed get hot and radiate light, but in a high vacuum every part of the bulb keeps perfectly cool, and the whole energy supplied seems to pass off in X-rays.

The following experiment is worth quoting at greater length.



A bulb like this with concave electrode, having at its centre a rather thick aluminium plate connected to it metallically (wires protected by glass), and beyond in its shadow the other electrode, was excited either with the cup as cathode or with the cup as anode, and pinhole photographs were taken simultaneously from various points of view, and at measured distances. A glass plate was subsequently put in the position of each of the sensitive plates, and the appearance of the tube as seen through the "pinholes" (which were ¼in. diameter), by an eye roving about, were drawn in ink upon the glass. The eye-picture thus obtained was afterwards compared with the developed images, and the sources of the radiation thus clearly observed.

When the small flat disc was cathode, every part of the complicated anode appeared strongly and quickly on the plate, especially the tilted and first bombarded portion on a plate placed above the tube. The cathode disc itself did not show at all. On a plate placed below the bulb the anode cup appeared strong, but the tilted disc did not appear. On the other hand it threw a sharp faint shadow *of the hole*, showing that its focus spot acted as a feeble point source, by reason of a few rays reflected back on to it from the cup.

When the current was *reversed*, the small disc anode showed faintly, being excited by rays which had penetrated the interposed tilted disc, but again the cathode hardly showed at all, not even the tilted portion on a plate placed below the bulb. By giving a very long exposure (two hours) some impression was obtained, about equal to that from the shaded anode disc; but, of course, if the tilted plate had been under these circumstances an anode, it is well known that a few minutes would have sufficed to show it strong upon the plate beneath.

Hence undoubtedly the X-rays do not start from cathode or from anything attached to the cathode, but do start from a surface upon which the cathode rays strike; whether it be an actual anode or only an "anti-cathodic" surface. Best, however, if it be an actual anode. I suggested the term "anode-rays," therefore, while Prof. S. P. Thompson prefers the term "anti-cathodic rays"; but probably the term used by Röntgen is still the best at present.

When the glass walls, instead of receiving cathode rays, are pierced only by the true Röntgen rays from the disc in the middle, no evidence is afforded by my photographs that the glass under these circumstances acts as a source. It is well that it does not, for its only effect would be a blurring one. With focus tubes the glass phosphoresces under the action of the anode or X-rays, as anything else would phosphoresce, but its phosphorescence is not of the least use. It is a sign that the tube is working well, and that the rays are powerful, but if by reason of fatigue the glass ceases to phosphoresce strongly, the fact constitutes not the slightest detriment. Not even when the glass itself is the first bombarded thing, and therefore itself the source of the Röntgen rays, does its fatigue make any difference. The fatigued portion of glass *looks* dim and unsatisfactory, while if by means of a magnet the rays are drawn aside from the fatigued patch on to a fresh portion of glass, the fresh portion *looks* bright and active; but the only radiographic result is that the source has shifted in *position*, as can be seen well enough by the shadow-parallax of suitably-disposed objects on a fluorescent screen; but no difference in *brightness* occurs. The fresh piece of glass glows brightly, and emits much more *light*; but it emits no more X-rays than the fatigued portion. I emphasise this statement because the contrary has several times been asserted.

The phosphorescence of the glass bulb is handy as an index, but it has no further advantage. The quality of the glass is doubtless of some importance, the lighter and thinner the better, one would suppose; and I doubt if *very much* advantage will be gained by replacing it with aluminium. I must say, however, that tungstate of calcium seems to me notably opaque to X-rays, and hence a non-fluorescent substance, or a less fluorescent substance than glass, may be really better for the walls of the tube. I anticipate that the use of uranium or other such glass would be a step in the wrong direction.

All the observations of the Discoverer have been confirmed by subsequent experiment, and the only additions that I am aware of to the list given by him are:—

1. The focus-tube: which is an old pattern of Mr. Crookes' merely more highly exhausted. I first saw it at work in Prof. Carey Foster's laboratory at University College, London, last January, and that particular tube still gives about the best defined results possible.

2. The use of potassium- instead of barium-platino-cyanide, or more recently the use of calcium-tungstate, as the fluorescent screen. Mr. Sydney Jackson, of King's College, seems to have done excellent and most useful work in this entire subject of fluorescence, as well as in helping everyone to acquire good and well-made focus-tubes by getting them put upon the market in a thoroughly well-exhausted condition.

3. The discovery of J. J. Thomson that the rays make insulators conduct.

It is sometimes spoken of as new that the rays discharge electrified bodies, but Lenard observed that in 1894. What had not been previously discovered was the reason why they do this. Many observations, more or less fanciful as I think, have been made as to whether positively or negatively charged bodies are discharged most rapidly; any such observation, to be dependable, requires extreme precaution, even if there were not the complication that nothing can be depended on to insulate when exposed to the stream of rays.

There is here evidently a large field for investigation, but any new results should be received with extreme caution, inasmuch as experiments on electrostatic discharge are open to such a variety of disturbing causes at the best of times.

Digitized by Google

It may be of interest to state that Prof. J. J. Thomson's discovery that the known discharging power of these rays for both positive and negative electricity is to be explained by the fact that they render insulators conductive, has been verified in my laboratory for one or two substances; but any differences between positive and negative discharge, and any difference between one kind of metal and another, remain in my judgment seriously open to doubt.

Another fact may as well be noted, viz., that platinum foil kept white hot by an electric current has practically the same degree of opacity as a cold piece. Five pieces cut from the same sheet were compared simultaneously; they were of different breadths and had the same current flowing through most of them, so that one was white-hot and one was cold, and the others were at intermediate temperatures, but there was no appreciable difference in their transparency. This, of course, tends in the usual direction of emphasing the importance of mere density; for hot and cold platinum must be considered as of appreciably the same density for the purposes of this experiment.

The crop of assertions about the detection of X-rays from all manner of absurd sources has somewhat dwindled of late, and the loss is a bearable one. A serious attempt must be made to observe if the sun emits them by exposing suitable objects, such as bullets imbedded in cork, in front of protected plates on mountain tops this summer. The atmosphere, being equivalent to over two feet of mercury, must entirely screen these rays from lower levels; but Alpine tourists have often reported a strange fogging of plates, which they have been disposed to attribute to the warmth of a guide's back!

The production of the rays has now reached a considerable pitch of perfection; there remains much good work to be done in the direction of their better detection, especially in their more rapid photographic fixing. It is true that a few flashes will now give a radiograph of a hand, but nothing comparable to the snapshot exposure which has been achieved in the case of light can yet be predicated of the X-rays. Their fluorescing power seems to show that they possess plenty of energy, and, of course, many attempts have been made to utilise this property directly, so as to make films more sensitive.

If the films themselves can be made to fluoresce, without otherwise being damaged, it *may* be a step in the right direction; but, so far as my experience goes, which is not far, a coating of fluorescent material near the film tends rather towards a scattering and diffusion of light—a poor exchange for the straightforward penetrating property of the X-rays themselves.

Nothing better than Röntgen radiation has ever been got for throwing clear sharp shadows and giving a dense clear image. Rays which cannot be refracted, nor apparently diffracted, nor even reflected to any appreciable extent, are splendid for bringing out sharp details, and any exchange of them for the diffuse glow of any kind of phosphorescent light may be a step backwards. Nevertheless, it is improbable that the present plates, put into the market for one purpose, are the best that can be devised for an altogether different, though allied, purpose, and much work of a somewhat empirical kind remains to be done by photographic manufacturers or amateurs before the most suitable kind of film is discovered.

EXPERIMENTS ON THE HALL PHENOMENON IN BISMUTH.

BY DR. A. LEBRET.

The Hall phenomenon, as we know, can be described as follows:—If we send an electric current (called the primary) through a thin plate of any metal, then it will be possible to find out on the edges of the plate any two points of the same potential. Joining these points in series with a galvanometer, then, of course, no current will be shown. After, however, exciting a magnetic field near the plate, the galvanometer does show a deflection indicating an electric current (called the secondary), and therefore a potential difference must have arisen by the influence of the magnetic field. The potential difference is due in no respect to any induction effect, as it does not disappear as long as the field remains magnetized. It is proportional to the strength of the primary current and to the magnetic force (to the latter only approximately), and, further, it depends a great deal on the metal used, being the strongest in bismuth and tellurium. Finally, it is inversely proportional to the thickness of the plate.

Hence the mathematical expression for the resulting potential difference is

$$e = \frac{M T C}{d},$$

and for the current passing through the galvanometer

$$i = \frac{M T C}{d r}.$$

M is the magnetic force, T the primary current, d the thickness of the plate, r the resistance of the secondary circuit, C the constant of the metal used. C, however, has been found to vary with temperature.

I performed an investigation on the Hall phenomenon in bismuth at the physical laboratory of Leyden under Prof. Kamerlingh Onnes' guidance. First, I examined the variation of C with temperature; secondly, I made some experiments on the dissymmetry of the Hall phenomenon for the opposite directions of the magnetic force.

The method of observation (Fig. 1) is somewhat different from the methods used by others, and the idea of it may be of use as well for other electrical investigations, especially

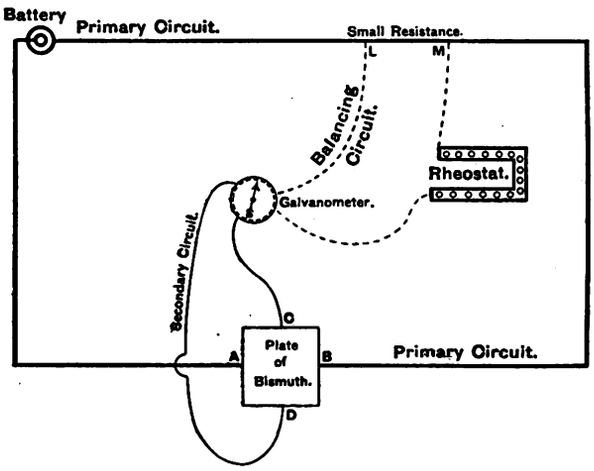


FIG. 1.—Plan of Method of Observation.

for relative measurements, as, for instance, variation with temperature. It consists chiefly in this—that the effect of the secondary current on the galvanometer needle is balanced by that of another electric current, which I shall call the "balancing" current, passing through a second coil of the same galvanometer. The two coils do not touch in any point, as do the coils of an ordinary differential galvanometer. The leads of the "balancing" circuit connect the ends of a small invariable resistance, joined into the primary circuit, in series with the second galvanometer coil and a resistance box, which allows the current to be adjusted. The strength of the balancing current is

$$i^1 = T \frac{r^1}{R},$$

supposing that the resistance r^1 joined into the primary circuit is very small (say 0·02 ohm), compared with the resistance R of the "balancing" circuit (say 100 ohms).

If the coils are in quite the same condition with respect to the needle (assuming which the explanation is a little simpler), then a balance obtained means that the currents are of equal strength; hence

$$i = i' = C \frac{M T}{d r} = T \frac{r^1}{R},$$

and

$$C = \frac{1}{R} \frac{r r^1 d}{M}.$$

Digitized by Google

The falling out of the strength of the primary current is not a small advantage of this method over the usual one, in which this current ought to be kept constant, and measured carefully. Besides, as mine is a zero method, the primary current has to be closed only for one moment in order to see if the exact balancing has been obtained or not, so that all heating and other disturbing effects, which require some time before becoming fully developed, fall away. All these are developed to their full extent in the usual deflection method.

For measuring the variation of C with temperature the magnetic field is kept constant. At another temperature the value of it (call it C_1) is given by the same formula:

$$C_1 = \frac{1}{R_1} \frac{r r^1 d}{M}.$$

We introduce only another value for the resistance (R_1) in the "balancing" circuit, the other quantities being quite or nearly constant.

Hence $$\frac{C}{C_1} = \frac{R_1}{R}.$$

So the constant of Hall is inversely proportional to the resistances to be introduced into the "balancing" circuit, and the variation of C is thus measured by the variation of $\frac{1}{R}$ only.

The results of the experiments on two samples of bismuth plates of different origin were not the same. The first (Fig. 2) was of very pure bismuth, in which no traces of other metals

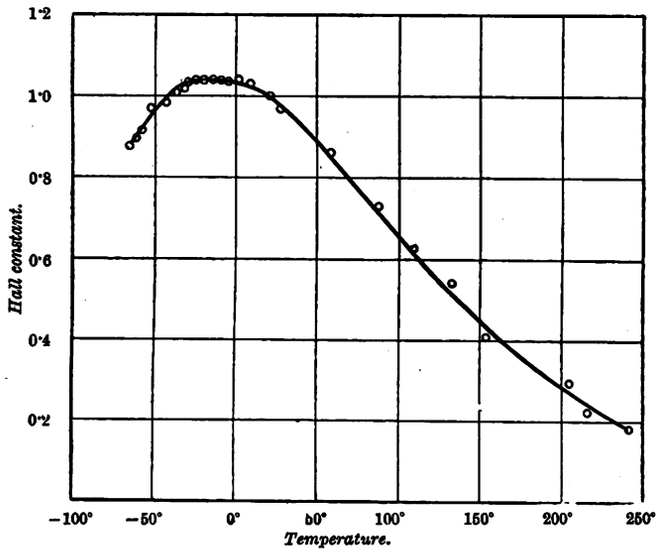

Fig. 2.—Variation of the Hall Effect with Temperature, in Pure Bismuth.

were to be found. The value of C at 21°C. was about 13 (C.G.S.) higher than ever was found before. This may be attributed partly to the purity of the metal used, and partly to the falling away, in our method of observation, of the disturbing effects which tend to reduce the potential difference.

The curve (Fig. 2) shows the variation with temperature. The most remarkable values of C, expressed in proportion to the value of C at 21deg., are, firstly, 0·175, the lowest one for 242·5deg., the highest temperature at which an observation was made; secondly, 1·040, the maximum value of C found at −12deg.; and, thirdly, 0·866 for −69deg., the lowest temperature attained.

Another sample of bismuth examined (Fig. 3) contained small traces of iron. The value of C at 21deg. was 7, as to show once more that the smallest impurity throws down the value of C to a much smaller magnitude. As concerns the variation with temperature, the lowest value observed was found at 246·5deg. to be 0·280 in proportion to the value of C at 21deg., and the highest 1·256 at −74deg., the lowest temperature at which I succeeded to make an observation. The form of the curve (Fig. 3) shows that this temperature cannot be far off from the maximum value of C which may be obtained.

A very important point connected with the Hall effect in bismuth is that the potential difference seems to rise to different values for opposite directions of the magnetic field. Von Ettingshausen and Nernst (see *Wiedemann Beiblätter* 11, p. 357, 1887) were the first who observed this; Hall (see *Sillim Journal* 36, p. 282, 1888) found this to be true, but hardly to be detected if the field does not rise above 8,000 (C.G.S.); and finally Van Aubel (see *Arch. des Sciences Nat. et Phys. de Genève* 33, March 15th, 1895) confirmed it, even for weak magnetic fields, but he supposed that the "dissymmetry" found was not a really existing physical quantity, but only the effect of an inaccuracy in the method of observation.

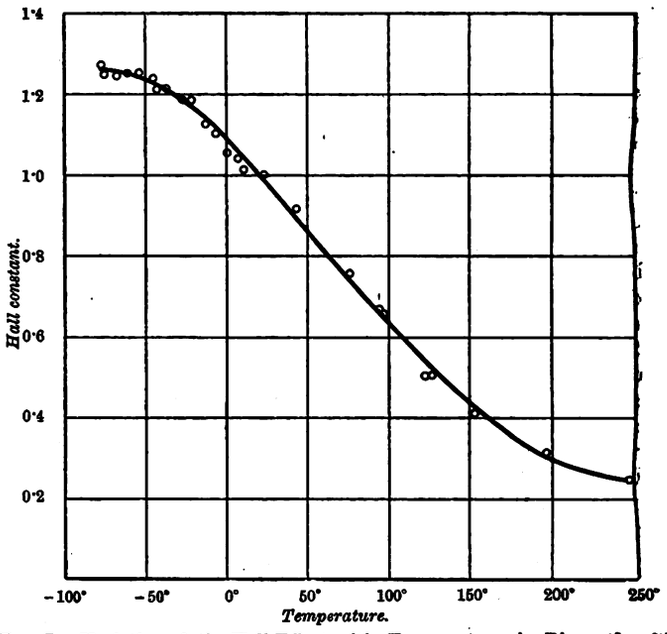

Fig. 3.—Variation of the Hall Effect with Temperature, in Bismuth with small traces of Iron.

The inaccuracy consists in the following:—The two points on the edges of the plate, to which the secondary leads are fastened, are not easily chosen as not to show a slight potential difference in a zero-magnetic field. Practice has given various means to redress this inconvenience. I myself used a wire joining a point of the positive side of the primary circuit through an adjustable resistance to the secondary lead of the lower potential (Fig. 4). So we can get the two points on the edge quite equipotential in the zero-magnetic field. Van Aubel makes an objection against this. The magnetic

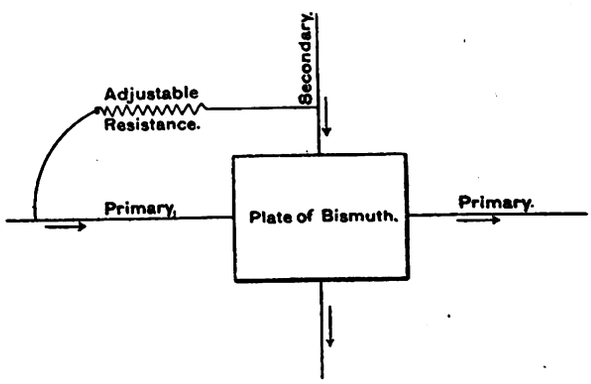

Fig. 4.

field, as we know, increases the resistance of the plate of bismuth. So only for this reason the equipotentiality shall fail to exist after the exciting of the magnetic field, and we should see a deflection of the galvanometer needle, even if the Hall phenomenon did not exist at all. This deflection would show itself always on the same side, not depending on the direction of the magnetic field. The deflection of the Hall phenomenon comes in addition to the former, and as it changes sign on reversing the magnetic field the resulting value is different for the opposite directions.

Digitized by Google

Van Aubel relied on this explanation, because he had found that after reversing front and back of the plate the greater deflection is shown by that direction of the field which had shown the smaller before. This really agrees with the explanation given. He expected that the dissymmetry should not be found in thick plates, as the increase of the small resistance of those would not disturb much the equipotentiality acquired before. The plate Van Aubel used was only some hundredths of a millimetre thick, and so of great resistance.

Although using very thick plates (3·5mm.), I observed the dissymmetry as well. Besides which, I found that in the plate of bismuth I used then, Van Aubel's explanation could not be right—for this reason, that according to it the potential difference ought to be the stronger for the direction of the field, which, in fact, showed the smaller. Finally, in order to be quite sure that no error could come in, I left out the wires with the adjustable resistance, the small potential difference existing in a zero-magnetic field being brought into account after the experiment was finished. The dissymmetry was observed again, and the ratio of the corrected readings found the same.

I examined carefully if any other error of observation or the influence of any thermomagnetic effect could account for the observed dissymmetry, but I did not succeed. Finally the following two experiments showed me in which direction the explanation was to be found.

First I changed mutually the primary and secondary leads, so that the primary current was sent through the plate in a direction perpendicular to the direction it went through before. I now observed that the potential difference arising by the magnetic field was the greater for that direction which gave the smaller effect before. We could say: the dissymmetry had changed sign without changing the absolute value.

Secondly, as the turning of the primary current direction at an angle of 90deg. makes the dissymmetry change sign, what should be the effect of turning it at another angle? Should the dissymmetry for any angle get a zero value? In order to examine this point I made a round plate of bismuth, which enabled me to fasten and unfasten the four leads at any points of the circumference where I liked. And after some trials I found out in which direction the primary current had to pass in order not to show any dissymmetry. This direction, which can be marked on the plate, we call an axis of symmetry. Another axis of symmetry is found perpendicular to the first. Directions between the axes show a dissymmetry, the sign of this being different in the first and third quadrants from that in the second and fourth. The dissymmetry gets to the maximum value for the direction which makes angles of 45deg. with the axes.

These results enable us to put the dissymmetry of the Hal phenomenon into a mathematical form. The Hall phenomenon itself is expressed by the formulæ:—

$$\frac{dp}{dx} = -ku - hv,$$

$$\frac{dp}{dy} = hu - kv,$$

in which p is the electrical potential, u and v the flow of electricity along the x and y axes, calculated per square unit; k is a resistance coefficient, and h a quantity depending on the material used and on the magnetic force, changing sign if the latter does, and having a zero value in a zero-magnetic field.

Suppose the primary current to flow in the direction of the x axis, then the potential difference of Hall arising by the magnetic force can be calculated to be $= h\frac{T}{d}$, where T means the strength of the current passing through the section of the plate, and d means the thickness. Reversing the magnetic field we have to give the negative sign to h, thus no dissymmetry is taken into account by the equations.

We have to vary the equations so that they do show the dissymmetry. We may best start with the axes of symmetry, for which the equations do not fail. Transferring to other axes would keep them in the same form unless there is a difference between the value of k in the first equation (call this k_1) and the value of k in the second (call this k_2). If there is then the calculated difference of potential for the axes of symmetry remains the same $= h\frac{T}{d}$.

Transferring now to other axes making an angle (say α) with the former, the equations become

$$\frac{dp}{dx'} = (-k_1\cos^2\alpha - k_2\sin^2\alpha)\,u' + \{-h + \tfrac{1}{2}\sin 2\alpha\,(-k_2 + k_1)\}\,v'$$

$$\frac{dp}{dy'} = \{+h + \tfrac{1}{2}\sin 2\alpha\,(-k_2 + k_1)\}\,u' + (-k_1\sin^2\alpha - k_2\cos^2\alpha)\,v'$$

and the calculated potential difference, if the current flows in the direction of the x' axis, becomes

$$e' = \frac{h + \tfrac{1}{2}\sin 2\alpha\,(-k_2 + k_1)}{d}\,T.$$

Reversing the magnetic field, we have to change the sign of h only. So we do not get the same value for the opposite directions of the magnetic field, and the dissymmetry results from the new equations.

The above-mentioned experiments agree with the values of the potential difference deducted from the equations. For if we turn the co-ordinates to an angle of 90deg. from the new position, then the dissymmetry changes sign. And the maximum dissymmetry results for $\sin 2\alpha = 1$, hence $\alpha = 45$deg., which is the angle found experimentally between the axis of symmetry and the direction in which we have to send the primary current in order to get the maximum dissymmetry.

So we are induced to assume that the magnetic field increases the resistance of the plate of bismuth in different rates for different directions (which can be marked on the plate). The directions of the maximum and of the minimum increase cut each other at right angles, and are axes of symmetry for the Hall phenomenon.

In connection with this I might remark that my plate, after the experiments were finished, was broken into pieces, and the cutting planes were found to be parallel for the majority. So the crystals of bismuth must have been parallel as well. It should be important to find out whether there is any relation between the crystallographic axes and the axes of symmetry for the Hall-phenomenon.

Experiments on the amount of the dissymmetry in different plates, or with different strengths of magnetic field, should be made after the direction in the plate being found for which the dissymmetry has the greatest value. I have made a few experiments on one plate with different strengths of the magnetic field:—

Strength of magnetic field.	Relation of the currents for the opposite directions of the field.
1,500	31 : 69
2,160	22 : 78
2,740	14 : 86
3,480	3 : 97

So the dissymmetry is quite distinct, and increases greatly if the magnetic field does. Experiments are going on at the Leyden University in order to get still higher values of the dissymmetry.

It has been proposed to measure the strengths of magnetic fields by the amount of the Hall current they should excite in a bismuth plate, standardised for the purpose. As yet this method has never been used in practice. More chance there will be, I think, that the strength of alternating magnetic fields might be measured by the amount of the dissymmetry effect which the alternating field excites. The plate of bismuth must be carefully standardised before use, with the aid of continuous magnetic fields, and, of course, the primary current is sent through in such a direction that the maximum value of the dissymmetry is shown.

Electric Traction in Germany.—The municipality of Darmstadt has just voted £32,500 for the construction of two electric tramlines on the overhead system, giving the contract to Messrs. Siemens and Halske.

COMMERCIAL ELECTROLYTIC ANTIMONY.

We learn from the pages of the *Zeitschrift für Elektrochemie* that Siemens and Halske are now preparing antimony by electrolysis, of considerable purity and in a convenient form. The samples which have been exhibited consist of dense grey plates of the metal, about 2mm. in thickness, and having the rugose and warty surface characteristic of antimony deposited from a thioantimonite solution, *i.e.*, a solution of antimony trisulphide in an alkaline sulphide. The side of the plates which has been next the cathode is smooth and bright, and the fracture of the metal is crystalline and brilliant. The plates are slightly curved and are very brittle, so that they can be readily powdered. As is evident from the following analyses, this electrolytic product is almost pure, and may be put on the market for most purposes without further refining, although it may also be fused into the customary ingots and slightly improved if desired.

—	Electrolytic antimony direct from cathode.	Cast metal prepared from electrolytic antimony.	Refined antimony prepared in the dry way.
Arsenic	...	...	Trace.
Sulphur.....	0·288	0·0001	0·1000
Iron	0·008	0·0046	0·0100
Lead and copper.	Trace.	0·0084	0·0303
Sodium	0·014	...	...
Antimony	99·690	99·9869	99·8587

Hitherto antimony has generally been sold as "regulus," *i.e.*, as cakes of the cast metal about 4in. thick, having the trade mark of the manufacturer on one side and the well-known "star" on the other. The crystalline appearance of the upper surface of an ingot of antimony is definitely stellar, and is taken by dealers as an index of purity, much as the "cry" of tin is accepted by traders in that metal. The value of these simple phenomena as a guide to the quality of the material is much overrated. A similar superstition exists in the galvanised iron trade, in which a crystalline appearance on the surface of the zinced plates is much esteemed, and is obligingly provided by the maker, irrespective of the quality of his wares. It may, therefore, take some little time to make buyers understand that antimony may be pure and yet destitute of a "star"; ultimately they may even be led to accept the crinkled surface of electrolytic antimony as a proof of quality, after which a natural step on the part of some enterprising person will be the preparation of thin plates of ordinary antimony, having their surfaces artistically roughened, which have never been in the neighbourhood of a cathode.

ON THE ELECTRIC CONDUCTIVITY OF CEMENT AND CONCRETE.*

BY DR. ST. LINDECK.

The disturbances caused by the leakage currents from the rail-return of electric tramways have of late been the subject of much discussion. Of the remedies proposed those should be preferred which not only overcome disturbances of a certain kind and at a certain place, but which attack the evil at the root, that is to say, diminish the leakage from the rails and consequently remove all kinds of disturbances at the same time. Prof. Ulbricht in a recent communication has given it as his view that even if we retain the rail-return system there are a number of ways of reducing the disturbances to a permissible amount. The most effective method, he considers, would be to increase the resistances between rail and earth. The amount of the earth currents is mainly conditioned by the relation of w_e/w_s, where w_e means the resistance between a unit of length of rail and earth and w_s the resistance of the rail itself for this unit of length. The knowledge of the electric conductivity of materials used for the foundation of electric tramlines is, therefore, of great practical interest.

Cement and Cement-Concrete.—The materials examined at the Reichsanstalt were parallelopiped blocks (Fig. 1) of 10cm. × 10cm. section and 40cm. length. About 3cm. from either end the electrodes E E', consisting of perforated sheet iron 8cm. × 8cm., with holes of 1 sq. cm., were embedded. In the middle, at e_3 and e_4, and also 10cm. on either side, pairs of strips (e_1, e_2 and e_5, e_6) of perforated sheet-iron 2·5cm. wide were arranged as secondary electrodes. This arrangement permitted an investigation of the uniformity of the material and of the distribution of the current. At least two blocks of each of the following materials were tested:—

1. Pure cement (Rüdersdorfer).
2. 1 part cement, 3 parts sand.
3. 1 ,, ,, 5 ,, gravel.
4. 1 ,, ,, 7 ,, gravel.

The resistance tests were generally made in such way (*see* Fig. 2) that a plug resistance box, W, a battery, B_1, consisting generally

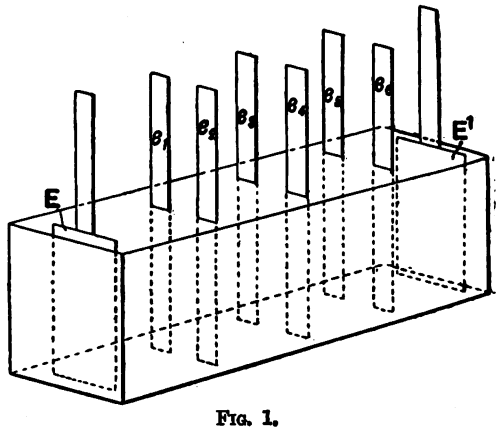

FIG. 1.

of 10 small accumulator cells, and the block X formed a circuit. The connections were made to the electrodes E E'. A Hallwachs electrometer, H, was employed for measuring the potential difference on the secondary electrodes of the block, and comparing the same with the fall of potential along a selected resistance of the testing set by means of the switch U_1. The needle of the electrometer was charged from the battery B_2 to a potential of from 50 to 90 volts. One pair of quadrants was earthed, the other was brought to the required potential. At each

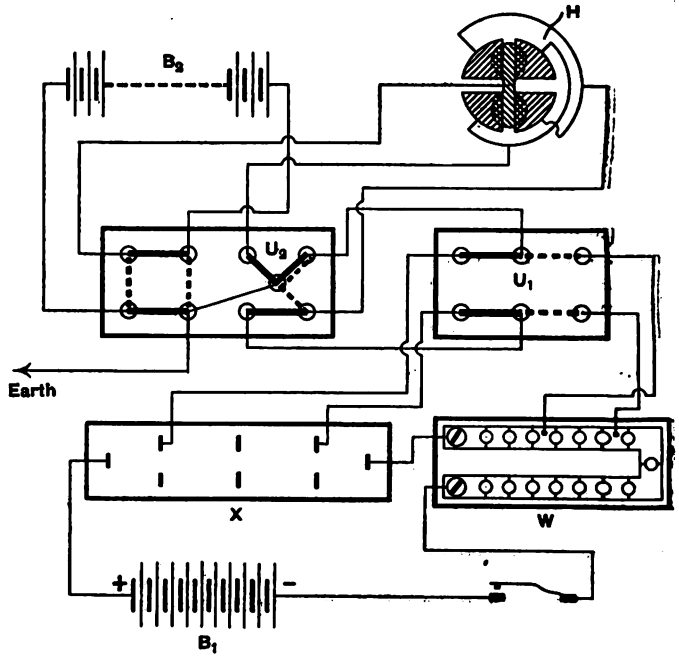

FIG. 2.

test the two pairs of quadrants were interchanged by means of the switch U_2. For the purpose of checking the numerous tests made with the electrometer, a galvanometer was employed having in series a resistance of 20 megohms. The results so obtained were identical with those obtained with the electrometer (*see* Tables).

The figures in the following tables give the results of tests made on blocks of the composition mentioned above. The blocks were made on July 8 and 10, 1895, and were allowed to thoroughly dry in the open, and it was only after 2½ months that the first tests were made. Two blocks (I. and II.) of each kind of material were examined, and on nearly all blocks the resistances between e_1 and e_5, and also e_2 and e_6 (*see* Fig. 1) were taken. For this reason there are provided in

the tables two columns headed *a* and *b*. The middle electrodes were only used for the purpose of checking, and it was found that the sum of the resistances between e_1 and e_3, and e_3 and e_5 approached very near the resistance between e_1 and e_5. For the reduction of the observed resistances to the resistance of a decimetre length of the material 1 decimetre in cross-section, the actual distances of the secondary electrodes were, of course, remeasured in each case. No special care was taken with regard to the temperature of the blocks; the readings given in the tables were taken with a thermometer, the bulb of which was in touch with the block.

From these tables it will be seen that the electric resistance of cement blocks and blocks made of cement and sand or gravel when in an air-dry condition is relatively small; it is lowest of all in the case of pure cement, and becomes higher as more sand or gravel is mixed with the cement. The porosity of the material increases, however, in the same proportion, as can be seen by the decrease in the resistance after the blocks have been put under water for some time. In this way the resistances of cement blocks fall, after being under water for about one day, to one-third of the resistance shown when in an air-dry condition. In blocks containing one part cement and three parts sand, a two-hours immersion

Digitized by Google

is sufficient to bring the resistance down to one-tenth of the original. And in the two kinds of concrete the resistance of the blocks when moist drops to about one-twentieth.

On the basis of these tests one cannot but come to the conclusion that the arrangement of the roadbed of electric lines must be very favourable to leakage, especially where the concrete on which the rails rest is covered with a layer of asphalt, which latter prevents a good drying of the concrete. The extent to which concrete retains moisture can be seen from the tests made on the blocks after they had been heated to over 100°C. for several hours. For instance, the resistance of a 1-decimetre length (1 decimetre square) of the compound, consisting of one part cement and seven parts gravel, rose to 6 or 7 megohms while in an air-dry condition, and three months after the manufacture the resistance was only 5,000 ohms. Similar results were obtained with the other concretes, but after one month's exposure to air the resistance fell to one-third of this figure.

In the cement blocks the change of resistance due to heating was small compared with the compound blocks. The resistance rose at first to 1,000 ohms, and further after one month to about 2,000 ohms.

If for the purpose of an approximate calculation the resistance of concrete in dry air is taken at about 5,000 ohms per 1 dm./sq. dm., a tramline put down on concrete would have a resistance to earth of under 1 ohm per kilometre.

Asphalt-Concrete.—Prof. Ulbricht's communication directed the attention also to asphalt-concrete, a material used to some extent for building purposes in Dresden. The same form and arrangements as for the other materials were adopted for this material, and the tests were made together with the others. Asphalt-concrete consists of 50 per cent. of stone chippings, 20 per cent. of rough gravel free from loam or sand, 12 per cent. of asphaltic mastic, 8 per cent. of pitch and 10 per cent. of German tar. The composition of the material can however be varied as desired.

It would be of little use to record here all the tests of the different blocks, as there was always an extremely high resistance, and one could never be sure whether one was dealing with the conductivity of the material, or only with surface conduction. For instance, a block made with "Syenit" chippings gave in dry condition per 1dm./sq. dm. 280,000 megohms. The block was then placed under water for two hours, and after having been again in the air for 2½ hours, it still showed a resistance of 160,000 megohms. Even after the block had been continually under water for six weeks, it still gave an insulation resistance of 17,000 megohms. Similar results were obtained with other blocks of asphalt-concrete. *The material is, therefore, practically wateproof.*

Summing up it appears most probable that by using asphalt-concrete the rails could be permanently insulated from earth to such an extent that leakage currents of any importance could not occur. The asphalt-concrete should be laid in a thin layer over the cement-concrete, so that the cost of a line would not be appreciably increased.

PUBLIC LIGHTING BY ARC LAMPS.*

BY ANDRÉ BLONDEL.

(Continued from page 759.)

Quality of Carbons.—The quality of the carbon has a considerable influence both on the voltage, on the production of light, and on their own duration. Not only the composition of the paste,[15] but also the methods employed in manufacture, and the temperatures employed in baking play a most important part. The proportioning of all these elements is more an art than a science; it is, properly speaking, a sort of culinary art, which only the initiated know how to accomplish, and even they have many failures, "wasters" occurring from one reason or another. I can only, therefore, offer very vague suggestion on the subject.

According to Mr. Marks[16] and Mr. Stine[17] a soft carbon gives more light than a hard one for a given amount of energy. But this is only true for short arcs; and if we are to accept the experience of French lighthouses, the contrary appears to hold for long arcs[18]. This is only natural, for everything which facilitates the volatilisation or deflagration of the molecules, as a rule, reduces the efficiency. French makers no longer make the distinction between soft and hard pastes, and their carbons all have but one baking. A high temperature appears to have the good effect of expelling all the hydro-carbons (which cause flaming), and of increasing the conductivity of the carbon. Wishing to develop these advantages as far as possible MM. Street and Girard recently tried the effect of re-baking the carbons in an electric retort, where they were partially turned to graphite. Carbons thus treated have special properties which appear to make them specially useful *as negatives.*[19] They may be considerably reduced in diameter without the consumption being increased. Some are employed with success in the shops of the Louvre. Then we know that to obtain a steady arc it is necessary to use a cored carbon for the positive, that is to say, it is necessary to use a carbon, the axis of which consists of a "wick" of some conducting mixture easily vaporised; by this means we can lower the voltage as much as we please, independently of the main body of the carbon itself. But this is done at the expense of efficiency, for the intrinsic brilliancy is also perceptibly lowered. I found, for instance, in measuring the mean brilliancy of the crater, that it is lowered from 160 candles per square *millimetre* to 120, merely by a very slight increase in the conductivity of the core.[20] But it will be objected that all these details cannot be foreseen when an installation of arc lamps is undertaken. It is not possible for the engineer to study the manufacture of carbons. This is perfectly true, and I should never think of suggesting such a study, which only makers can undertake, and in which, moreover, chemical analysis is almost useless.[21] But there is a far simpler method, and that is to note the results. We see on one side that carbons last the stated time and burn regularly with a steady arc. From this we can form some idea of the value of the carbons, as we can also by measuring the range of play, that is to say, the variation of voltage, which is possible without causing either hissing or flaring. To this end we ascertain the voltage at which the arc hisses, and then the higher voltage at which the flame appears. A badly-baked carbon which hisses at 50 volts and flares at 55, may with better baking only hiss and flare at 42 and 60 volts respectively. A good cored carbon should not hiss with more than 35 volts or flare with less than 60. We can satisfy ourselves as to the homogeniety of the carbons by ascertaining by means of a recording apparatus that the variations of current or of the potential difference between the carbons do not exceed, say, 5 per cent. A photometric measurement should also be taken. Not a measurement at this or that angle, but a spherical measurement of the total luminous flux or of the lower hemispherical flux should be made by the aid of a *lumenmeter.* I am quite aware that I am now going contrary to practice, which is to define arcs by the energy they absorb. This may be a very easy method, but it is absolutely irrational, and calculated to hinder all progress. Is it just that we should impose no test on that part of our system which transforms energy into light, while we impose conditions of Draconian severity as to the efficiency of the machines which produce the energy? Is it not ludicrous to quarrel about 2 per cent. in dynamo efficiency, while we allow variations of from 100 to 200 per cent. in the lamp? From this point of view every saving in the cost of carbons which is effected at the expense of their quality is one of the most unfortunate we can possibly imagine. I will assume, then, in that which follows that we have first of all obtained a good efficiency in the production of light, for it is only on this condition that the improved equipments admit of the energy being well utilised.

Equipment.

Fittings for Public Arc Lamps.—Without troubling here as to the construction and form of the lamp-posts, I will consider the form of the envelope covering the lamp, the reflectors which may be fitted in it, and the optical equipment of the lamp generally. The arrangement of these fittings depends on many circumstances. The ease of handling, economy in up-keep, elegance—fashion even—play a great part in the choice of fittings. But for my present purpose I can easily single out a small number of appliances, such as the following:—

Polygonal Lantern.—The arc lamp is placed in a lantern similar to those used for gas. There are only a few examples of this fitting, for instance, on the Newsky Perspective in St. Petersburg

* From *La Révue Technique.* Translated by Mr. John Hesketh.

[15] The paste of European carbons consists of a mixture of retort coke, lampblack and tar; the core of a mixture of charcoal and alkaline silicates. In America petroleum coke is much used in the paste, but the quality of the carbon is inferior to ours. The proportion of these elements greatly modifies the conductivity and other properties of the carbon.

[17] *Electrical World*, February 25, 1895, p. 223.

[18] See notice on the apparatus exhibited at Chicago in 1893 by the Service Central des Phares, and "The Electric Arc Light and Machinery of Lighthouses," by A. Blondel. International Maritime Congress, 1893, see *The Electrician*, Vol. XXXI., September 1, 1893, p. 428.

[19] For positives both the electrical and calorific conductivity are too great; the arc is too unstable, and too great a portion of the carbon gets red.

[20] *The Electrician*, Vol. XXXII., December, 1893, "On the Continuous-Current Arc."

[21] My friendly colleague Mr. Debray, professor and director of the Laboratoire d'Essais at l'Ecole des Ponts-et-Chaussées, has been good enough at my request to make an analysis of a series of samples of carbons of different makers, each presenting widely different practical properties. He found that the chemical composition of the pastes was almost the same for all the samples. To distinguish any difference it would be necessary to separate out the different kinds of carbons. This is a most delicate test, and one which can be undertaken by very few industrial laboratories. M. Girard has made a number of tests of this nature in his work on graphitic carbons.

Digitized by Google

(Fig. 6) and in the City of London (Fig. 7). This type has many practical advantages, such as easy access to the carbons by opening the door of the lantern, perfect shelter for the lamp and ability to change each pane of glass in case of breakage. It is frequently used in lighting railway stations. Fig. 8 illustrates the lantern used by the Midland Railway Company.[22] The simple reason, in my opinion, why this lantern is not more used for public lighting is

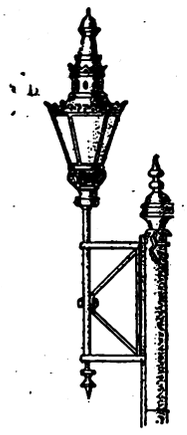

Fig. 6.—Newsky Perspective Lantern.

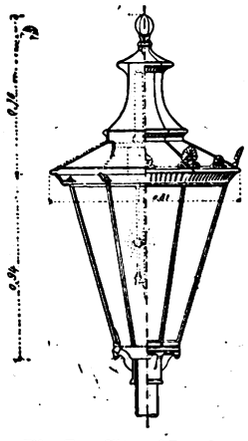

Fig. 7.—City of London.

because it is ugly. Certainly a lantern such as that used in the City of London, when it is fitted with opaline panes, is most inelegant. The type used in St. Petersburg is more acceptable, and the arrangement for sliding the lamp up and down the post is very ingenious. But it is easy to see that the polygonal lantern can never have the same elegance as our Parisian lyre. This type of

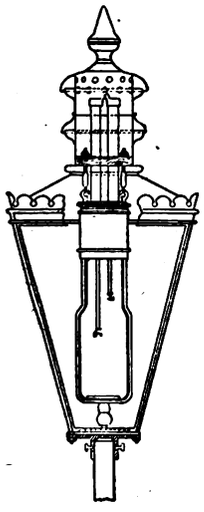

Fig. 8.—Midland Railway Company's Lantern with, fluted glass.

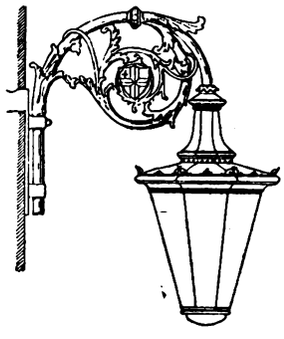

Fig. 9.—Wrought-iron Bracket and Suspended Lantern (City of London).

lantern is also open to the objection that it leaves a dark space at the foot of the post; an inconvenience observed in London. Such a lantern, if suspended (Fig. 9),* enables us to escape the shadow, and seems by far more elegant than if fixed on a pillar. Lanterns forming part of the lamp itself (Fig. 10) are out of the question

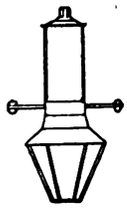

Fig. 10.—Lantern used in Docks, &c.

entirely, and should never be used except in yards, docks, &c. A metallic reflector is often placed inside lanterns when there is sufficient room; of these I will speak later.

* The figure is taken from Major-General Webbers' well-known paper on the lighting in the City.

[22] This last arrangement allows the lamp to be lowered through the bottom of the lantern in case of repairs, which is a far easier method than lifting it through the top.

Plain Globe.—Lamps fitted with a simple spherical or oval globe are suspended in the same manner as when used for interior lighting. The method of suspension may be either by a cable crossing the road to be lighted, by a bracket, or by a bishop's crook or crosier (Figs. 11 and 12), all of which arrangements avoid

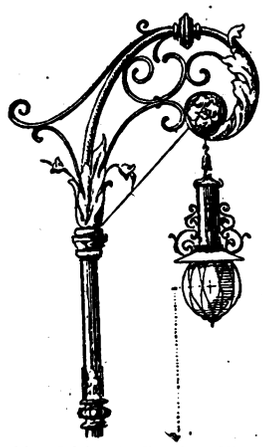

Fig. 11.—Bishop's Crook. Fixed at Ulm by Messrs. Schuckert.

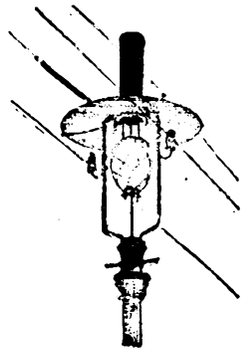

Fig. 15.—Marienbad Lyre, with Reflecting Shade.

shadows at the foot of the lamp post. Suspended lamps may also be fixed in a light lyre-shaped carrier, which does not detract from the beauty of the arrangement and hides no light (Figs. 13 and 14). The shadow at the foot of the lamp exists, however, unless the lamp is sufficiently raised (Fig. 14). The advantage of these arrangements is the economy, the lamp having no accessories, so to speak.

D

Trimming is generally done by lowering the lamp, either by a winch or by tilting the post on a knuckle-joint and removing the globe, as is done in the interior of buildings. The æsthetic effect is not

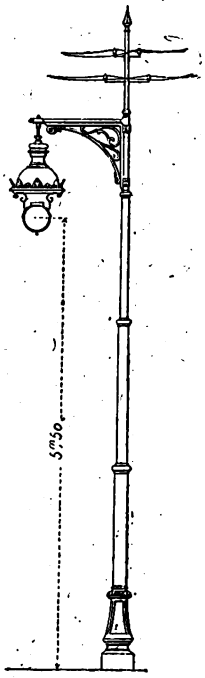

FIG. 20.—Post and Suspended Cupola.

bad, but the general appearance is rather skimpy. The chief objection is that the lamp and globe are poorly protected against wind, rain and snow[23]; a hood is therefore often added to shelter the globe (Figs. 12 and 15). The appearance then is much less graceful. These fittings are chiefly employed on the Continent, but very little in France. They are much in favour in Germany, Italy

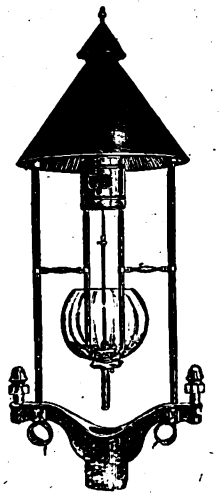

FIG. 21.—Thomson-Houston Lamp, with Hood.

FIG. 22.—Hood of Brush Lamp.

and Switzerland, where very light and graceful lyres are to be found (Figs. 16 and 17). In England, on the contrary, these patterns have been modified so as to make them more substantial,

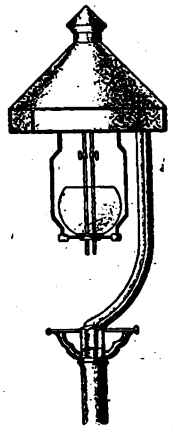

FIG. 23.—Chicago Hood.

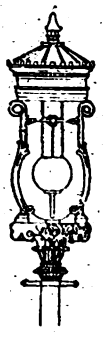

FIG. 24.—Lyre and Cupola at Chicago Exhibition.

but certainly at the expense of their artistic aspect, if we may judge from Figs. 14 and 18, which though very convenient, are not the most attractive examples of lanterns for use in an important city.

FIG. 26.—Lyre and Cupola at Blackpool (by Smith and Sons, from designs by J. Hesketh)

FIG. 27.—Three-armed Carrier at Brighton (Crompton).

Globes with a Cupola or Dome—This type is, from many points of view, the most practical. The globe is well shielded, the lamp may be perfectly hidden, and if necessary the dome may be fitted

[23] This arrangement is therefore without *raison d'être*, unless it is opted with a view to avoiding the use of a ladder.

Digitized by Google

with a reflector. The dome and the lamp contained in it may be fixed on any kind of post, or suspended from a cable, or from a bracket by a hook (Figs. 19 and 20). The globe may also be spherical or oval. From the artistic point of view, very different

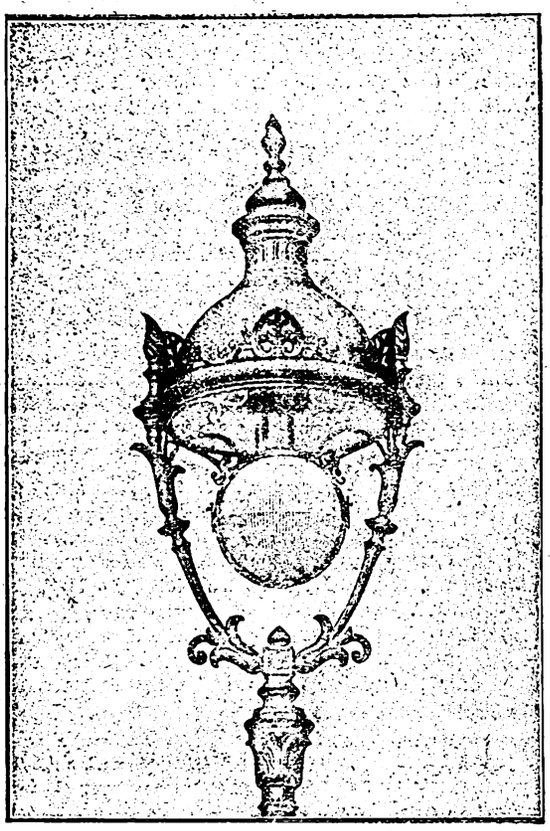

Fig. 25.—Lyre and Cupola as Used on the Paris Boulevards.

results may be given by this type of carrier according to the fancy of the makers. They are most ugly in America, as shown in Figs. 21 to 24; but in Europe, and particularly in France, where this type is used almost to the exclusion of all others, they are very elegant. The lyre and dome of the boulevards (Fig. 25) is

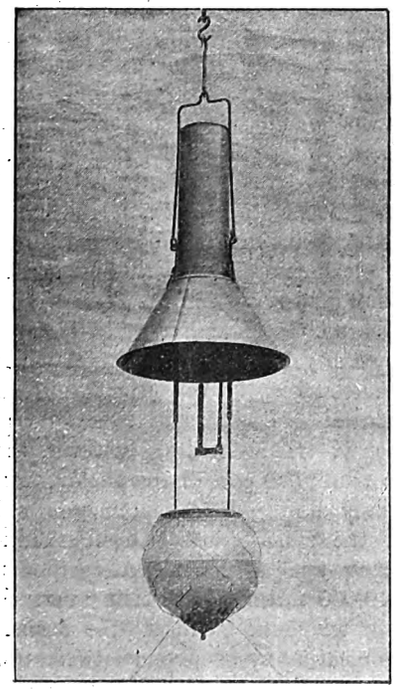

Fig. 28.—Lantern of the Port of Havre, showing Method of Moving the Globes.

now adopted in most French cities, and is sure to become the chief type for urban lighting. In Germany this type is little used; but it is beginning to be adopted in England. Figs. 26 and 27 show two recent examples, which are certainly very elegant and deserve high praises.

When this type of carrier is used,[24] the trimming is done in one or other of the following manners:—(*a*) The globe is cut vertically into two halves, and is opened like a lantern for cleaning and trimming (Fig. 25). This method is adopted in Paris and many French towns. (*b*) The globe is kept intact, but may be moved to give access to the carbons, either by suspending it from two chains, as shown in Fig. 28, or sliding it down a globe carrier, as in Fig. 26. (*c*) The globe is divided horizontally, and the lower half only can be moved.[25]

Almost all lyres carry enamelled reflectors, to which I will refer later. Care should be taken that the globe carrier is sufficiently long to reduce the shadow cast by it to a minimum, and for the same reason the thickness of the arms of the lyre should be reduced as far as possible. These are the principal types of fittings at present in use.

Problem to be solved in the Utilisation of Light.—The problem to be solved is simply: To diffuse the light in the best possible manner; that is to say, to soften the brilliancy so as to allow the eye to take in as great a part as possible; and distribute it in the most advantageous manner. Light sent above the horizontal plane of the lamps is generally lost. Neighbouring houses reflect it only in an imperfect manner, and besides, the occupants of the rooms above the lamps are generally anxious to be relieved of the annoyance of having the arcs constantly under their eyes[26]. We should then, in general, endeavour to send down all the light below the horizontal and distribute it according to a theoretical law, closely following that indicated in my "Theory of Public Lighting" (see *The Electrician* Vols. XXXV. and XXXVI., October and November, 1895). We may form an opinion of the comparative value of this or that type of fitting for lamps by calculating the luminous *efficiency* which it attains. This efficiency is the ratio of the *useful flux of light*, *i.e.*, the light which each lamp fitted with all its accessories sends out below the horizontal—to the *total flux* produced by the arc employed.

(To be continued).

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

MONDAY, April 13th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Royal United Service Institution, Whitehall.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting at the Palatine Hotel, Hunt's Bank, Manchester. "Lecture and Demonstration of the New Photography with Lantern Views," by C. M. Dorman. After the Lecture the Members of the Society will visit the Manchester Corporation Battery Station on the invitation of Mr. C. H. Wordingham.

TUESDAY, April 14th.

ROYAL METEOROLOGICAL SOCIETY.

7:30 p.m Ordinary Meeting at the Institution of Civil Engineers, Great George-street, Westminster,

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be read: (1) "The Thirlmere Works for the Water Supply of Manchester," by G. H. Hill; (2) "The Vyrnwy Works for the Water Supply of Liverpool," by G. F. Deacon. At this meeting the monthly Ballot for Members will be taken.

WEDNESDAY, April 15th.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Meeting at 20, Hanover-square, W.

THURSDAY, April 16th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Recent Chemical Progress," by Prof. Dewar, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Discussion on Mr. Dane Sinclair's Paper: "Telephone Exchanges and their Working."

FRIDAY, April 17th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Colour Photography," by M. G. Lippmann.

[24] That which follows applies more generally to all lamps fixed in lyres, even though without cupola or dome.

[25] Most of the lamp-posts used in France are made by Messrs. Durenne, of Auteuil, who have made a speciality of this class of fitting.

[26] This is still another reason for avoiding very high arcs in narrow streets.

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 8s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. *[Nearly ready.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. *[In preparation.*

FULL CATALOGUE POST FREE ON APPLICATION.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field: Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; Dr. Heinrich Hertz; Mr. R. E. B. Crompton; William Sturgeon; and Dr. John Hopkinson, F.R.S., have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound n strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d. post free 13s. 6d. Many of these Volumes are very scarce.

THE TELEPHONE AND THE POST OFFICE.

The transfer to the Post Office of the trunk line telephone wires, which took place on Monday last, has been described as the commencement of a new era in the history of telephony in this country. To us it seems rather only one stage further in a development which has been proceeding with singular slowness for many years past, and which at the same rate will take as many more to reach its culminating point. Except that the Post Office Department will now be in still closer relations—relations amounting almost to a partnership—with the National Telephone Company, there is really nothing new in the position of affairs. From the Company's point of view these relations are close enough already, seeing that they are represented by a royalty of over £70,000 per annum which the Company have to pay for the privilege of doing the telephone business of a Department which does nothing but pocket the money. Henceforward, however, the Post Office will work the trunk line part of the business itself, the wires of the Company having been purchased, and fresh ones erected, with the sums granted by Parliament for that purpose as long ago as 1892. Altogether there is said to be about 40,000 miles of trunk line wire now available for that kind of telephone business—the business, that is to say, of communicating by telephone between town and town, as distinguished from that of speaking from one part of a town to another part of the same. The town exchanges will continue to be under the management of the Company, the accumulated charges for conversations passing over the inter-urban lines being divided between the two partners, the Post

Digitized by Google

Office, needless to say, taking the biggest share, based, no doubt, on the practice of the Company itself, which made a heavier charge for using the trunk wires than for the local service.

The National Telephone Company having already erected the larger portion of the wires now to be worked by the Post Office, it will be seen that nothing very startling has occurred. There has been a transfer of plant and a sectional change of management, the section appropriated by Government being the trunk lines. The public may feel assured that so far as these lines and those to be speedily taken over, or be erected hereafter are concerned, the service will be rendered with the same efficiency which characterises the telegraph service. But the service over these wires under the old management was not a ground of complaint—or at all events not by any means the most serious—against the Company; and it is rather hard to understand why Parliament or Post Office elected to take over that part of the business and to leave the other alone. There are no trustworthy statistics available on the subject; but we may safely assert that trunk wires are the least used and the most costly part of the telephone business; and that consequently the less remunerative part of it will be the reward of the Government for its timidity. It is a case of not cancelling the "charter," but assuming authority over a branch of the administration which involves greatest responsibility with smallest returns. Let us hope that the local exchanges may not prove to be Matabele for the Post Office. This danger, it seems to us, is by no means a fanciful one, for the satisfactory working of the trunk lines must necessarily depend largely upon the condition of the exchange systems with which they are connected, and every obstacle occasioned by the latter will be sure to be credited to the connecting links, the Post Office getting all the blame. If this should result in greater influence being exerted over the Company to the improvement of the local services the public will congratulate itself on the change. But it must not be forgotten that the Government have all along had the power to do this, but have never exercised it, and we are by no means sanguine that what has happened now will bring about any radical improvement. The *rôle* of sleeping partner does not lend itself to active interference, and we fail to see how that activity will be aroused by becoming a bed-fellow.

The false position in which the Post Office allowed itself to be landed at the outset is one from which it can never be extricated save by assuming absolute control over the telephone system in its entirety. Any lingering doubt as to the actual as well as legal identity of the telephone and the telegraph was dissipated when the Company began to construct trunk lines. From that moment it also became clear that the Government could not indefinitely refrain from taking over those lines, which would otherwise become a formidable rival to the older method of communication. Logically it would follow that the town exchanges, which are said to have injured the telegraph revenue very considerably, should also fall into the hands of the Government. But reasons outside the sphere of logic have so far protected the National Telephone Company in its local strongholds. We need not enumerate; the objections to acquisition by the State of an enterprise such as these exchanges represent are manifold, and for a long time to come will be potent. Mr. Goschen's allusion in 1892 to a vast army of State telephone officials is enough of itself to frighten Parliament for another decade at least. This being the case, we may dismiss for the present all thought of transferring to the State the remaining property of the National Telephone Company. And so far as we can see there is no desire for it on the part of the public, who would be perfectly content if the Company would, or could, provide a better and cheaper system for local purposes. We do not attach too much credence to the public complaints on this subject, and we gladly offer our testimony that things have lately improved somewhat. But when all allowances are made, the local telephone systems of this country are far from being what they should be, both as regards tariff and efficiency, compared with those of some other countries. We cannot boast of the telephone service as we do of the telegraph service; and we naturally ask why these two, so closely related with the government of the country, should continue so different in merit.

One reason may be that the Post Office is reluctant to interfere with or hamper a Company which yields a handsome revenue to the coffers of the State—a circumstance which, if true, illustrates very clearly the anomalous position of the State in its relation to the Company. The suggestion has been made that the right to issue fresh licences should be freely exercised by the authorities, and that at least this right might be advantageously exerted in favour of Local Authorities, some of whom, it is understood, would be only too glad to start business in competition with the existing company. A very good case would have to be made out for it, however, before any Postmaster-General could be induced to grant such licence even to an enterprising County Council. Failing the Local Authorities the next best thing to do would be for the Post Office to acquire absolute control over the plant, and *farm out* the working of it. The Department does this already on a large scale in respect of Post Office business, over which, nevertheless, it exercises complete administrative authority. The arrangement is profitable to both parties; and it seems to us not beyond the bounds of possibility that the same principle might be applied to the working of local telephone exchanges without vastly increasing the number of State paid officials. Not that they need cause any very serious alarm in a country like this where they have as yet no connection with political movements; but it is best not to take steps, which cannot be retraced, in a direction leading towards a grave public danger, and we cordially agree with Mr. Goschen as to the inadvisability of augmenting the army of civil servants when it can be avoided.

REVIEW.

Electric Wiring. By Russell Robb. (New York and London: Messrs. Macmillan and Co.)

This book is designed to put before architects, underwriters and the owners of large buildings the main principles of electric light and power supply, with especial reference to fire risks, and it is intended for use in America. The contents have appeared during the last two years in a series of articles in the *American Architect and Building News*. The first four chapters, which deal with generalities, have but a limited application to English practice, and the last chapter, which contains the National Code of Rules for Electric Wiring, with special comments and explanations by the author, is, of course, applicable solely to American practice. In the introduction there is a very readable comparison between electric and hydraulic power, which although not always scientifically true, serves to convey a fair idea of the main facts if not of the phenomena underlying them. Indeed, the author rightly assumes that there is no need for his readers to try to master the subject as experts. He says: "It is largely a matter of familiarity, and it is doubtful that our knowledge of the ultimate meaning of pounds and feet is much clearer than our knowledge of volts and amperes." We

Digitized by Google

cordially agree with him. Generally the technical information is conveyed in concise and clear statements, without the not unusual confusion between power and energy, but there are some curious slips, which we mention only to ensure amendment in a second edition. On page 15, after a discussion upon the heating of conductors by an electric current, and a summary of the results as regards loss of pressure and waste of power, we are told "it is partly because of these facts that wires of inadequate sizes are so often used." The author's meaning may be clear enough from the context, but his language does not convey it, and we can imagine a non-technical reader's amazement at the literal statement. In several places, too, we find that volts are multiplied by amperes, with the results that watts are produced. Such arithmetic feats may be understood of the multitude, but they are a blot on a useful book. The author evidently feels the need of consulting engineers in America. On page 26 he says:—"In a large building there is opportunity for a good grade of engineering skill, and to have this work done by anyone except those who have studied this branch of engineering and who are familiar with its requirements is sure to result in loss." We echo this sentiment, if we do not quite agree with the terms in which it is couched.

To an English engineer the interesting part is that referring to the National Code of Rules in use in America. There appears to have been a revolution in wiring practice in the United States, unless the rules are more honoured in the breach than the observance, as, perhaps, our "Rules" are on this side. Some of the requirements are even more severe than those in practice here. For example, the use of flexible wire for "show windows" (presumably shop windows) is prohibited in America, while here there is probably not a shop served by electric light which has not one or more of such fittings. In connection with interior conduits, it is interesting to note that unarmoured conduits are not considered as insulation between conductors and earth, and that, therefore, the insulation of the conductor must be of the same grade as if wood casing were used, and only a single conductor is allowed in each conduit. It follows as a corollary to this rule that the use of twin conductors is prohibited for this class of work. If we mistake not, that form of cheap wiring was suggested as being quite efficient and safe at the recent wiring discussion at the Institution of Electrical Engineers. In connection with fuses and switches, it is noteworthy that the requirements of the Phœnix Fire Office are adhered to. Double-pole fuses and double-pole switches are required on all important sections of the installation.

In fact the general practice so strenuously advocated by Mr. Musgrave Heaphy is practically adopted *en bloc*, and new restrictions are added.

THERMAL EFFICIENCY OF STEAM ENGINES.

At the ordinary meeting of the Institution of Civil Engineers on Tuesday, the 24th inst., Sir Benjamin Baker, K.C.M.G., the President, in the chair, a Paper entitled "The Thermal Efficiency of Steam Engines" was read by Captain H. Riall Sankey, R.E. (retired), M.Inst.C.E. The question of the standard with which the results of steam-engine trials should be compared, had occupied considerable attention in several Papers on steam-engine economy which had, during the past 14 years, been read and discussed at the Institution. The matter was, nevertheless, in an undecided condition, and the author expressed the hope that discussion on this Paper might prepare the way for the adoption of some definite standard. He urged that in order to obtain full information of the thermal performance of an engine, two efficiencies had to be stated, namely, the absolute thermal efficiency, and the "standard" thermal efficiency, the latter denoting the comparison of the actual engine with an ideal steam engine working within the same temperature limits. In other words, the "standard" thermal efficiency was the absolute thermal efficiency of the actual engine divided by the absolute thermal efficiency of the ideal steam engine chosen as the standard. It was the choice of this standard which had caused so much discussion. Many views were held as to what should constitute the ideal engine required for this standard of comparison; but the author considered that the true object of such a standard was to provide ready indication as to how far the particular engine under consideration fell short of what was physically possible within the limits of temperature by which the engine was bound, having regard also to the varying temperature at which the heat was supplied to the feed water. It was shown that this requirement was met by the Clausius "perfect" steam engine, slightly modified, however, as regards the point to which the expansion was carried, for practical reasons which were universal and permanent.

To assist in a decision as to the standard to be adopted, other ideal engines which had been proposed or used as standards were considered; for instance, the Carnot cycle; the engine whose expansion line was the saturated steam line, and the engine the expansion line of which followed the law pv^n = constant; and in each case it was pointed out in what respects the requirements of the standard were not fulfilled. This comparison was also made by means of the $\theta\phi$ chart.

After considering certain points in connection with the various lines of the indicator diagram of the standard in greater detail, the author proposed the following as the standard of comparison:—

1. Admission line at the temperature of the steam at the stop-valve of the engine;
2. Expansion line adiabatic, and carried to within 0·15 atmosphere of the back-pressure;
3. Back-pressure: that in the exhaust immediately outside the engine;
4. Compression nil, and clearance nil.

The object of limiting the expansion, as suggested, by carrying it down to within 0·15 atmosphere of the actual back-pressure was to obtain a compromise between the two following conditions:—If the expansion were carried to the back-pressure, the standard would lead to the use of engines too large for their work; if, however, the expansion in the standard were only carried to a pressure equal to the back-pressure plus the mean pressure (referred to the low pressure) corresponding with the friction of the actual engine, a premium was, so to speak, awarded to a stiff engine, and the standard would be made to vary with the stiffness of the actual engine. To avoid the lengthy calculation of the absolute thermal efficiency of the proposed standard, curves had been prepared enabling the required result to be obtained by inspection, and numerical examples were given to show the method of application.

The author pointed out that in many cases a comparison of the actual engine with what he proposed to call the "type" standard was useful. The type standard was an ideal engine which took into account the clearance, compression, back-pressure, &c., necessary with the particular type of engine under consideration. For instance, the ideal engine with an expansion line following the saturation line was the type standard for a jacketed engine. The difference in the amount of heat utilised by the standard and the type standard showed the unavoidable loss normal to the particular type of engine, whereas the difference in the heat utilised by the type standard and the actual engine gave the more or less avoidable loss. The proposed standard was applied to the case in which super-heated instead of saturated steam was used, and the $\theta\phi$ diagram of this standard was given, and two numerical examples were worked out.

It was pointed out that the actual commercial criterion of a steam engine's economical performances, namely, the number of pounds of water per indicated horse-power, led to errors of about 1 per cent. as a maximum when using saturated steam; but that the error might be as much as 13 per cent. when superheated steam was used. This difficulty would be met by stating the amount of heat required per indicated horse-power, as proposed by Mr. Mair-Rumley in 1882.

The Paper was accompanied by appendixes demonstrating the use of the $\theta\phi$ chart for finding the absolute thermal efficiency of the proposed standard engines and an investigation of the efficiency of the fluid in heat engines in general.

BOILERS AT ELECTRIC LIGHT STATIONS.*

There is a cause for everything, if not a reason. It is not always easy to see what the cause may be, or to be satisfied with the reason. But the fact remains. In electricity manufactories or electric light stations, whichever they may be called, it is noteworthy that steam is generated on a system different from that which has for half a century at least satisfied millowners, and indeed manufacturers of almost all known commodities. For ordinary manufacturing purposes the Lancashire or the Cornish boiler is used almost to the exclusion of all other types. The former is no doubt an excellent example of the survival of the fittest, and its all but universal adoption is the result of a careful calculation based on commercial principles. From the first, however, the Lancashire boiler has been almost absent from electric light installations. It is only recently that it begins to be used in a tentative fashion by electric light engineers. In not only the United States, but this country

* From the *Engineer*.

Digitized by Google

as well, we find that boilers of the water tube or locomotive type are nearly always employed to drive electrical machinery. There must be some reason for this. We do not think that it has ever been stated; but it does not seem to be far to seek, and when found it is instructive.

When electric light stations were first designed in this country the designers were in almost every case electricians, not mechanical engineers; or at least not mechanical engineers possessing any considerable commercial knowledge of the working of steam machinery. These gentlemen knew from books that high-pressure steam was more economical than low-pressure steam, in the sense, at least, that a smaller weight of the former than of the latter would give a horse-power, so it was determined that high-pressure steam must be used. But the Lancashire boiler was not deemed suitable for pressures over 100lb., so recourse was had to water-tube boilers; and to locomotive type boilers because it was a familiar fact that on our railways pressures of 150lb. and more were regularly carried. It is no disparagement of the water-tube boiler to say that the results of its adoption have not been uniformly satisfactory. It is, for one thing, peculiarly exigent in its demands for good water, and in the second it is very expensive to keep clean, and if not kept clean the tubes split and leak. The locomotive boiler, again, is a very admirable steam generator, but it, too, has its peculiarities. It is the full consciousness of these things that has induced mill-owners to resist all temptation to use any other than the double-flued or Lancashire boiler, which has been recently so proportioned that it will carry any pressure asked for. Indeed, it should be almost self-evident that if a marine boiler 15ft. or 16ft. in diameter can carry a pressure of 160lb., there ought to be no difficulty in making a Lancashire boiler of half the diameter equally strong. The mistake committed by the electrical engineers has been in assuming that the boiler which made steam most readily and was most economical in the consumption of coal must be the best. It is just the species of error into which the non-commercial engineer is likely to fall. The truth is that coal represents but one item in the cost of making steam, and it is not invariably the most important item. The price to be paid for water is not infrequently very large; and ever high-priced water may not suit either water-tube or locomotive boilers. Then there is the question of wear and tear, the quality of the steam produced, and many other matters which must all be considered before it is possible to say what is the best type of boiler to put down; and all this, be it noticed, has nothing whatever to do with the qualities of the boiler regarded from the theoretical point of view.

To make our meaning quite clear, let us suppose that a sum of £500 is available for the purchase and erection of a boiler. We may obtain with this a Lancashire boiler which will work well and give satisfaction for 10 years, with very moderate repairs, and be nearly as good and serviceable at the end of that time as it was at the beginning; or we may get a locomotive boiler which will need heavy repairs before half that period has elapsed, and will be good for very little at the end of the term. Or a water-tube boiler, which will last for half a century, simply because it has new tubes put in, a few at a time, all the year round, every year of its life. All three may be of equal evaporative efficiency, but even if they were not the millowner would keep to the Lancashire boiler, not only because it would, in the long run, be much the cheaper of the three, but because it would always be ready when wanted. It would seldom, if ever, be laid off for repairs. No doubt it may be urged, and urged with truth, that both the water-tube and locomotive boilers are excellent steam generators. This does not affect the question in any way. All the experience available goes to show that over a series of years the Lancashire boiler will be found less costly in upkeep, and more trustworthy than any other type of land boiler in the market; and that this truth is gradually coming home to electrical engineers is demonstrated by the circumstance that recourse is now being had to the Lancashire boiler in very important installations, to an extent, indeed, not dreamed of a few years ago—that at St. Pancras, for example, which we illustrate this week. It must be understood that in writing as we do, we are simply bringing before our readers certain considerations often overlooked, and endeavouring to find a cause, if not a reason, for the remarkable departure from normal practice which marked the advent of the electric light in this country. It can scarcely fail to strike any thoughtful man as remarkable that types of boilers scarcely known in Great Britain should have been used to the exclusion of all other types for supplying steam to electric light engines. Outside of railway shops no locomotive type boilers could be found driving stationary engines of more than a comparatively few horse-power. In factories they are practically unknown. The water-tube boiler fought for its life in Great Britain. All over the kingdom, in spinning and weaving mills, pumping stations, factories of all kinds, many rolling mills of the largest size, nothing was used but the Lancashire boiler. But with the new light all this was changed, and we had not only the electrical experiment, but the steam generating experiment as well, and it is not remarkable that the results were not always quite satisfactory.

It would not be fair, however, to attribute the adoption of the locomotive type or the water-tube boiler either to caprice or theoretical knowledge alone. No doubt installations were often constructed under circumstances that rendered it next to impossible to use anything but the water-tube boiler. There are places in the Andes where no part of a steam engine or boiler must weigh more than 200lb. Everything has to be carried on mule back. There are places in great cities into which it is equally impossible to convey any large structure. For such places the sectional boiler is simply invaluable. But this scarcely suffices to explain the favour which the locomotive type of boiler enjoys. It is not because only such a boiler can be forced, and other reasons must be found for its adoption. That it requires no brickwork, and is an excellent steam maker, are no doubt points very much indeed in its favour; but, when all this has been said and admitted, we have still to face the fact that for places were large demands are made for steam, day after day, nothing is so popular as the Lancashire boiler, or its modifications.

Those who can read the signs of the times know that the production of electricity on a small scale in numerous establishments will have to give way to its manufacture wholesale, on a great scale. That which has become possible at Beckton with gas may become equally possible with electricity. The question will then force itself on engineers, What is the best method of manufacturing steam? It is not wise to prophecy until after the event. Yet we are rash enough to say that probably the Lancashire boiler will be used in conjunction with mechanical stokers, the smallest possible amount of manual labour being employed. In settling this question it must not be forgotten that the demand for power becomes more and more uniform the larger the installation, and, consequently, the wider the district served. "The peak" does not occur, for instance, in all existing metropolitan installations at the same hour. This consideration will have an important influence on those who have to select the type of boiler to be used. Furthermore, the heat storage system introduced by Mr. Druitt Halpin may modify conditions of service very considerably. In saying this we do not wish, as we have said before, to be understood as finding fault with any particular type of boiler. Our object is to record what may be termed the drift of public opinion. It does not follow that we regard the water-tube boiler as inferior to the Lancashire if we state as a fact that mill-owners prefer the latter, and that electrical engineers in taking to the former have departed from precedent. The doubt and hesitation which exist are fairly well exemplified on a small scale at Islington, where Mr. Gay has put down both Lancashire and water-tube boilers almost side by side. It must, too, be borne in mind that nearly all the electric light stations in this country are comparatively young, and few opportunities have yet been afforded for testing the actual life of a boiler. Our purpose will have been served if we have succeeded in directing the attention of our readers interested in the manufacture of electricity to the fact that a considerable departure from normal manufacturing practice has marked the progress of the electrical engineer, and that many more things than the production of steam have to be thought of when ordering a boiler.

THE REGULATION OF PRESSURE AND THE REDUCTION OF LIGHT LOAD LOSSES IN ALTERNATING CURRENT SYSTEMS OF ELECTRIC SUPPLY.

The following is an abstract of the discussion which followed the reading of Messrs. E. W. Cowan and A. Still's Paper before the Northern Society of Electrical Engineers (see *The Electrician*, April 3, 1896, p. 762):—

DISCUSSION.

Mr. RIDER said he should, first of all, say that he had listened to that Paper and read it with deep interest. So far as the first part of the Paper was concerned, in dealing with the regulation of pressure, he was fully in accord with the authors. In the "Thomson" diagram the size of the feeder which worked out as most suitable for that particular current came up to 19/14. Taking the maximum current at 71 amperes, which was given in the Paper, that came to about a density of 750 amperes per square inch, which was a very safe working current for a feeder. He fully agreed with the statement that the size of the feeder should be determined by the current it had to carry, and that the drop should not be taken into account at all, as by the Thomson law the loss per mile due to the drop increased in the same ratio as the cost of the feeder. With regard to the regulation of the feeders, the method the authors had drawn their attention to was one which he (Mr. Rider) was at present using, and he could speak of it in the highest degree. He would like to point out that it was only applicable, and could only be used to keep the pressure at the feeding points absolutely constant when the different feeders and networks were distinct from each other. If they had one network and two feeders feeding at different points, they could not keep the pressure exact at

Digitized by Google

those two feeding points under such conditions. They would have to cut the network, each feeder would have to serve its own network, and not be connected with any other. They then came to the second part of the Paper. He was afraid that there was a good deal of debatable matter in it. A scheme which he (Mr. Rider) was putting down had been mentioned, that was of using accumulators in connection with a motor-alternator. He was not at present able to give any figures, because they had not started, but the Society must get his successor to give them a Paper, and he would no doubt tell them more truth about it than he (Mr. Rider) would. The various points brought before them wanted very carefully thinking about. It was recommended that for a light day-load plant a separate steam pipe should be used. He presumed that it was meant that the main steam range should be cut off during the day. If they turned the steam on suddenly to a large steam ring they ran the risk of breaking the joints. He believed in having steam on right up to the stop-valves of the engines the whole of the time, otherwise they might have a big smash. The scheme which was brought before them for reducing light-load losses was no doubt very interesting, and the figures which were given were very plausible, but he could not altogether see through them. The authors mentioned that they found a saving of 17 per cent. in the horse-power when running through this augmentator, having the engine speed reduced two-thirds, that was 17 per cent. of saving; it was not 17 per cent. of the full horse-power of the engine. Supposing the engine was 100 H.P. it was a very bad plant if it took 20 H.P. to drive it at light load. If they took 17 per cent. of the 20 H.P. it only brought them to about 3·4 horse-power, which was not a very great saving. He thought the best way would be to put in a much more efficient plant, say an open coil alternator with no iron in the armature rather than using one with heavy losses. Surely if an alternator with no iron in the armature was awkward to run parallel with the iron cored machine which they had at heavy load, that difficulty would only come in at the time of paralleling to change over, as the small plant then could be stopped. It was suggested that the governors of the engines should be arranged so that they would give the variation of speed mentioned. He wished to see the governor which would enable them to alter the ratio one-third and still have a good range of governing. He thought if they had governors which would give an adjustable range of 5 per cent. they were good governors. This method of reducing losses only took into account the losses at the station, and did not affect the losses outside—in fact, they were going to increase the losses outside, and when their station became a large one, and the number of transformers very large, that method would be in a still worse place, because heavy losses would be going on all the time outside. With regard to the question of altering the frequency of arc lamps and meters. Last year at Bolton they reduced the speed of the whole of the plant 17 per cent., not on account of the alternators, but for reasons which were purely mechanical. They brought the periods down from 100 per second to 83 per second. They had a number of arc lamps in the town, and they had not to alter the regulation of a single one—in fact, they burnt better. With regard to the meters, some of the meters were made for 100 periods, and he thought that some of them would be reading a bit out at the reduced periods. He made careful tests, and put in series with these meters other meters specially made, and he found practically no difference at the end of the quarter, taking the ordinary working load on the meters. They were Chamberlain and Hookham and Shallenberger meters. The Paper said that as there were no alternating-current motors in use they need not be taken into consideration. He (Mr. Rider) said alternating-current motors were in use in many stations, and if a station had only one motor in use, the result of such a procedure as lowering the speed of the plant every day would be to damn the system.

Mr. MORDEY said before speaking on the Paper he wished to be allowed to say a word of explanation. In the report of their last meeting he read that the President had done him the honour to regret his absence, and that the author of the Paper, Mr. Hammond, did him a similar honour. The fault was scarcely his. He was not a member of the Institution, he had had no notice of the meeting nor copy of the Paper, either from the Society or from the author, nor had he been invited, so that he could hardly have been expected to be present. With regard to the matter before them, he wished to join in congratulating the authors on the Paper, which was an excellent one—he wished they had more such papers in London. A great many points were touched on, but he must confine himself to a few of them only. With regard to the first paragraph, he quite agreed with the plan the authors advocated, and which was shown in Fig. 4. It was a very good one, and one which in many cases had advantages. The Brush Company used it a great deal. He thought it was Mr. Dawbarn of his Company who first introduced it, and they found it convenient and simple. Ideas as to "banking" transformers had changed; they did not get very much advantage if they used transformers above a certain size. In a 12 or 15 kilowatt transformer they got a no-load loss of between 0·75 and 1 per cent., and no matter how large the transformer might be the loss did not go much below that, so that there was no advantage in efficiency in having very large ones. And as to the cost, the lower price per kilowatt of larger transformers had to be set against some extra cost in mains and inconvenience in handling. It might be hypercritical, but he wished to object to the capacity current being spoken of as being in advance of the E.M.F. He knew it was the universal way, but it was wrong; it gave a wrong impression. The ordinary, or he might say, the general explanation given of the difference between self-induction and capacity was that self-induction caused the current to lag behind the E.M.F., while capacity caused it to lead or be in advance of the E.M.F. He once heard an eminent Professor explain that self-induction was something that when the E.M.F. was applied delayed the flow of current, while capacity was something which sucked the current out before the E.M.F. was applied. This amounted to saying that the effect preceded the cause. In the interests of clearness of perception of the physics of the matter, he wished to protest against this way of speaking of the effect of capacity. What really happens is that the current is caused to lag still more by capacity than by self-induction—the capacity current lags so much behind the wave of the E.M.F. producing it that it is just in front of the succeeding E.M.F. wave. For mathematical purposes it may be convenient to consider it as in advance of the E.M.F., but it must be remembered that this does not correctly represent the fact. Instead of saying it was a quarter period in advance of the E.M.F. it would be physically more correct to say that it was three-quarters of a period behind the E.M.F. The authors alluded to an excellent method of regulating shown in the various diagrams 3 and 4. He thought that the arrangement of the Manchester Company or of Mr. Rider was an excellent one; it did not differ in principle from what had been seen before, but he thought it was the most practical way of applying the principle. With regard to the saving of power when the pressure was raised by apparatus of that sort, he might mention a fact from his own experience. In one station with which he was acquainted it was necessary to raise the volts. He found, on going into the question as to whether there would be a loss of power, that there was a saving of power. He found that by raising the volts by an augmentator the actual power absorbed by the alternator and the augmentator was less than by the alternator alone if worked up to the full E.M.F. He mentioned that as illustrating the effect of the apparatus which was called a "hitcher-up." There was another point in connection with "hitching-up" which was perhaps of some interest. There had been a good deal of discussion as to whether they ought to have self-induction or not in alternators. He had always thought the less they had of it the better. If for no other reason, for the very sufficient one that it spoiled the "characteristic" of a machine, and made regulation troublesome and difficult. When working normally there was no need for self-induction, but there were perhaps certain abnormal conditions under which self-induction might be of service, if the required effect would not otherwise be obtained. For sample, they had two alternators without self-induction, and put them in parallel when they were out of phase, causing a more or less violent shock under current. If they had attempted to lessen the shock by giving the machines a good amount of self-induction they would lessen the shock, but the machines would regulate badly; they would have a large drop in the E.M.F. when the load was increased. With an augmentator, however, with the fine wire across the mains, and the thick wire in series with the alternator, they had self-induction, but it was only self-induction when the machines were out of step. At other times it had no effect on the regulating qualities of the machine. This was a valuable feature in his opinion, in connection with the use of augmented alternators. An important matter was raised by the proposals to reduce the losses in alternators at light load. He rather agreed with Mr. Rider's criticisms on the proposals. He thought the whole point of the diagram No. 7 was that the machine was an unfortunate one for the purpose. He did not mean to say that it did not illustrate the proposal well, but he was quite sure that the authors would not put it forward as a machine that had other good qualities than that of showing the need for reducing its no-load losses. He was rather in favour of reducing the engine losses at light load than the alternator losses. Of course, engines could not be run with very small loads, but in cases where it was necessary he thought that the losses even of a large alternator were so small that the probability of using a small engine should be considered in connection with some clutching device by which the alternator would be driven in the day time by the small engine and at night by the large one. He might illustrate what was said about the careful lagging of the cylinders by referring to a recent experience he met when he was carrying out a test. As the people who built the engines were very anxious to get good results, they had every door and window closed. He was assured by the man in charge of the engine that if they had the doors and windows open there would be a very perceptible increase in the amount of fuel consumed. He suggested that they might put the engine into the feed water tank, so that the lost heat might be recovered. He thought it was a mistake to suppose that a machine without iron in the armature they got such a very large current on short circuit. As a matter of fact, the current on short circuit with an armature without iron in it was not or need not be more than with machines with iron cores. In his own machines they always short-circuited the terminals with full steam on, and the current usually did not rise above three times, and he had never yet seen it more than five times the full working current. They had learned by experience that they must make machines to stand short-circuiting, and had had no difficulty in doing so without losing the good regulating quality which he thought, next to safety, was of prime importance to central station engineers. The first thing to have, after safety, was a machine with the smallest possible fall of potential and self-induction. Just one word before he concluded on the subject of reducing speed. If the authors would consider that the light-load dynamo under most circumstances was running a large number of transformers, and was fairly heavily loaded, even with no lamps on, he thought that they would see that a reduction in the speed was not advisable, because the total transformer loss would increase more rapidly than the alternator loss would diminish. This would be the case at least in stations where the day-load dynamo and engine were fairly proportioned to their load.

Mr. STATTER said with regard to diagram No. 2 he would like the authors to tell him why they limit the money to be spent on the feeder to the copper. It seemed to him that they ought to be able to spend as much per annum on the losses in their feeder as they incurred by way of interest on the total sum expended in materials and in the labour for laying the same, plus an allowance for depreciation in getting the current from point to point. He supposed that in central station work it was a very difficult matter to fix upon the size of conductor, because they did not know what the requirements in the future would be. But if Thomson's law was used at all, then 10 per cent.) the authors' figures for interest and depreciation) of the total cost of the feeder and of laying it should be plotted,

Digitized by Google

instead of 10 per cent. of the cost of the copper and insulation only, as plotted by the authors.

Mr. WORDINGHAM said the first point he wished to refer to was with regard to the fourth method of distribution described in the Paper. He thought the authors were certainly right in saying that it was the most convenient and best way of distributing; at the same time, in case of a short on the mains all the fuses might go, and it would be a terrible nuisance to get them back quickly, and there would be a very serious interruption in the supply, whereas if they had the transformers in sub-stations they could very rapidly get their fuses replaced. He thought the position the authors had taken up about the most economical size of feeder quite unassailable. The current density, which had been worked out in that diagram, was about what he believed to be the best density they could find; it was about 750 amperes per square inch, which agreed fairly well with his own practice. He generally used 600 amperes. With regard to the device for showing the potential at the end of a feeder, which the authors said was largely used in America, he believed that that was due to Dr. John Hopkinson; that method was introduced and patented by him many years ago. He thought that that might be of interest to mention, as they did not like to get their ideas from America. The same consideration that occurred to Mr. Rider about the steam pipe occurred to him also; he did not think it was really practicable to shut off the main steam range for any part of the day, unless they were sure to have ample time to have it on again. If they had a sudden demand, and the range was shut off, the the result would be disastrous. He might say a word with regard to the reliability of ejector condensers. At the Manchester station they had them on all their engines, and they had never had the slightest trouble with them, and they had given excellent results.

Mr. NISBETT said he would like to protest against diagram No. 2, which in his opinion was entirely misleading, owing to the fact that the cost of laying the mains, armouring, making good the pavement, &c., had not been included. It was obvious that because these were standing costs, whatever size of mains you lay, they should not be left out, for when the main is worn out the armouring is worn out, and the trench is also worn out, and therefore depreciation on these should be added to that on the cable. This allowance would make the economical current density very much higher than the authors supposed. Taking the same example as the authors had done, viz., an average current of 26 amperes, adding to the cost of the cable that of the armouring and trenching, the economical section of copper would be 0·03 of an inch instead of 0·1, so that at heavy load that cable would be working at a density of 2,500 amperes per square inch. The authors, on the other hand, had taken the cost of energy lost in the cables at 1½d. per unit, whereas they had taken the energy lost in driving the pumping and other plant at something like ¾d. per unit, because they said the standing costs were not in such case chargeable. Of course the same reasoning applies equally to the losses in the mains, it being only the coal bill which is increased. If now they add to the interest and depreciation on the cost of the cable the amount due to the trenching, armouring, &c., and reduce the cost per B.T. unit lost in the mains to ¾d. instead of 1½d., it was at once obvious why Thomson's law was not more generally adopted, at any rate, for high-tension mains, for the law shows that the economical section is such that if it were used the mains would be red hot at load time every evening. There were one or two points in connection with the system of distribution marked D. He could not altogether see that it had many advantages over the system C. Mr. Wordingham had raised a point about the difficulty of getting at fuses in transformer pits. That was a very important one. The contacts on transformers were very apt to get loose. He considered the scheme with sub-stations far preferable. All the contacts could be seen and examined periodically with ease, and the facilities for switching transformers in and out as the load varies were better. Both systems, however, had their uses. Then the authors laid too much stress altogether on the amount of capacity current. They calmly talked about a capacity current of 10 amperes on a feeder. That would mean that the feeder would have to consist of 25 miles of 19/18 cable. He thought that they had put down to cables that which belonged to the transformers. He agreed with the authors as to the necessity for regulation on feeders, and the apparatus designed by them seemed to answer its purpose admirably. With regard to the remark as to the cost of pressure wires, these were not so great as the authors seemed to think, as a pair of pressure wires can be put into a high-pressure cable for about £35 per mile, which is not a very serious item. He did not agree with the authors as to the economy of injectors. He thought that they had rather contradicted themselves as he read it. Apparently they had overlooked the losses due to the condensation of steam and the necessary re-evaporation of the water; the pulsometer pump was an instance of that, and, although a useful form, he did not think anyone would say it was a more economical form than a barrel pump. It seemed to him that a good pump of the ordinary type, driven by an electric motor, was far and away better than any injector.

Mr. HESKETH said he thought that engineers at last saw the futility of seeking for an absolutely uniform day load, and the authors were now attacking the question at the right end in seeking instead for high efficiencies at low load. Certainly any central station engineer who settled down to solid work after hunting the phantom of a day load, would find that those little economies were very difficult to obtain—even more difficult, perhaps, than the day load. With regard to the question of boiler efficiencies, the efficiency of a boiler increases as the duty is lowered. He obtained about 9·5lb. of water per pound of coal when evaporating 9,000lb. of water, but reducing the evaporation to 6,000lb. of water he got 10½lb. of water per pound of fuel, showing a great advantage from not pressing the boilers, or using rather large boilers for low duty. As to cutting off the steam range, he found that the losses in the steam ring were getting very considerable, and tried the natural expedient of cutting it off during light load time, but unfortunately the cost of repairing joints was double the cost of keeping steam up There is also a great deal of loss in the use of feed water heaters. It is a very common practice to put a large feed water heater in the main exhaust pipe, and expect that they were going to get the full advantage of the whole of the heat units in the exhaust steam. That was a great fallacy. The same economy would be obtained by using the exhaust steam from their pumps to heat the feed water and condensing the main exhaust. If they so used the exhaust of their steam pumps, the losses in driving feed pumps by steam were not so great as they would at first appear. The steam taken by the centrifugal pump mentioned by the authors would not be 1 per cent. of the total steam taken by the engine, although its power might be 1 per cent., but the steam would be something between 5 and 10 per cent. The method of reducing engine losses by reducing the speed was rather drastic, and he would rather use an alternator without iron in the armature. They had one or two motors at Blackpool, and to alter the periodicity every day would cause such trouble that they would have no peace at all. One of the greatest requirements in central station working was absolute confidence of the consumers in the supply; and if they were going to vary their speed every day, of course the consumers would never put up with it. As regards the low-tension distribution in scheme D, he said that they had experimented with short circuits recently at Blackpool to see the effect, and found that the fuses acted immediately, and cut out the faulty section.

Mr. LINDLEY said that on the question of the reduction of the speed he thought that, apart from the difficulty with the springs which Mr. Rider had foreshadowed, there was the difficulty that they would have to stop the engine to alter them again before it could be put in parallel with the other machines. He would like to suggest what might be done to meet that difficulty. It was not advisable to reduce the speed of the engine providing you could put up with having the alternator running at its full speed. The whole thing really centred on how much they could reduce the power of a compound engine without seriously falling off in the economy; this in a suitable engine should be one-fifth of full load, and then there would be no necessity to reduce the speed of one of the smaller units in order to operate the day load with economy. He might suggest to Mr. Mordey, who had been kind enough to offer to teach them something about putting engines into the feed water tank, that he, Mr. Mordey, might have put the steam pipes in also, so that they would get a higher efficiency still.

Mr. STILL said, in reply, that Mr. Cowan and he had been prepared to meet with a good deal of opposition, as there was no doubt they had laid themselves open to attack from various quarters. The way in which the Paper had been received was a very agreeable surprise, and he wished to thank those present, both on his own behalf and on Mr. Cowan's, for the kind way of which they had spoken of it. He proposed to reply to the points raised in the first part of the Paper, and Mr. Cowan would then deal with the second portion. He was glad to learn that Mr. Mordey had found the system of distribution shown at D in every way satisfactory; it certainly seemed to him very superior to the system of sub-stations with a heavy low-pressure network, which, neither from the point of view of economy or of regulation, made proper use of the many advantages of a high-tension supply. With regard to Mr. Wordingham's remarks, that in the case of a short circuit all the fuses might blow, this was only applicable to the case in which all the secondaries of the transformers are connected in parallel, by closing the switches marked S, which would most decidedly be the wrong thing to do. In reply to Mr. Statter, and notwithstanding Mr. Nisbett's great confidence in his own assertions on the subject of Thomson's law, it is quite evident that in working out the most economical cross-section of a feeder, the capital cost we have to consider is only that portion of the total capital outlay *which depends upon the amount of copper in the feeder.* Mr. Nisbett admitted that the laying of the mains, making good the pavement, &c., were standing costs, and did not depend upon the size of the cable, and this was the assumption which has been made in the Paper; but Mr. Nisbett still thought that the amount of these costs should determine the size of the feeder. Why then should he stop at the culverts and trenches and not include transformers and sub-stations, or even the cost of the generating station itself. The wearing out of the culverts or pipes and the cost of keeping these in order was a question of the choice of the system, not of the exact cross-section of the cable to be used. If the extra labour of drawing in a heavy cable is worth considering it should undoubtedly be taken into account, as also should the *increased* cost of the culverts, &c., if these have to be made larger in size as the cable increases in weight. The most convincing argument of all in support of their contention, that though capital costs which are constant cannot affect the economical size of the cable, was one which every mathematician would appreciate at once. In order to obtain the minimum value of any quantity which is a function of another variable quantity, he differentiates both sides of the equation, and since the differential coefficient of a constant is zero, there could be no trace of this constant left in the differential equation, and it was therefore quite impossible that it should influence the size of the feeder. Mr. Nisbett mentioned excessive temperature rise as a possible limit to the size of feeders worked out on Thomson's law, but in practice this was not found to be the case, and for that reason it had not been referred to in the Paper. If a dangerously high temperature were likely to occur at times of full load, two or more cables would have to be laid side by side, or the cross-section of the single cable increased, according to which method proved to be the most economical. Mr. Nisbett also spoke of feeders as being buried in the ground, but this was bad practice; they could always be drawn into pipes or laid in culverts, where they were easily accessible, and could be added to when required. With regard to the 10 amperes of capacity current referred to in the Paper, this was merely assumed in order to work out an example, but as a matter of fact a capacity current of 8 to 10 amperes, or even more, was by no means impossible or unheard of, and Mr. Nisbett seemed to forget the existence of rubber-insulated cables, which, with their

Digitized by Google

thin dielectric of comparatively high specific inductive capacity, took far more capacity current than paper-insulated cables. The current due to the capacity of the cables was a totally different thing to the magnetising current of the transformers, and there could be no confusion between the two. Mr. Mordey, on the subject of capacity current, objected to its having been spoken of as a quarter-phase in advance of the E.M.F. This, however, was the usual way of expressing what was really the truth, and the question was, after all, only one of the choice of terms. There were, undoubtedly, two ways of expressing one and the same thing, and it was, of course, quite correct to speak of the current as lagging three-quarter phase behind the E.M.F., but when dealing with the phase differences between two periodically varying quantities, there was no beginning and no end to be considered, and the displacement of one of these quantities with regard to the other could surely be expressed with equal accuracy either by stating the amount by which it was in advance of the other, or by the amount by which it lagged behind.

Mr. COWAN, in reply, said that Mr. Rider, Mr. Wordingham and Mr. Nisbett had all criticised the suggestion that steam ought to be cut off the ring main during the hours of light load, as they did not believe it was practical on account of the failure of joints likely to arise. If that was the case, why was it that cylinder cover joints did not give similar trouble? He thought that if the joints were properly made and the steam pipes properly suspended, such trouble ought not to occur. Of course great care must be exercised in admitting steam to a comparatively cold range of pipes, in the matter of draining, &c. It could not be done in a hurry. There seemed to be considerable doubt in the minds of many of the speakers as to the advisability of reducing the speed of the engine. Mr. Mordey and Mr. Lindley seemed to think that the object was to save losses in the alternator. This was not so; the saving effected was only in the engine, nothing was saved in the alternator. A good deal was made of the increased losses in the transformers which would, of course, arise with the lower frequency. This point had been, he submitted, effectually answered in the Paper. When the time came, when the day load plant was loaded with a very large number of transformers, the only saving in the reduction of speed might be in "wear and tear," and it might not be considered worth while to continue the practice. He did not think there would be any great difficulty in designing a governor which could be adapted to control the engine at two different speeds. The tension of the springs should not be altered, but the leverage at which the weights acted; and the alteration must, of course, be made by hand without stopping the engine. Mr. Lindley preferred an engine which gave nearly equal economy at all loads, from one-fifth to full load. But the question was not one of thermodynamic efficiency only, but *brake horse-power* compared with steam consumed. An engine which gave nearly equal economy at from one-fifth I.H.P. to full load was the right kind of engine to install for light load, but the saving due to reduction of speed was effected with that engine as well as with any other. On the question of the results of the reduction of frequency from the consumer's point of view, the only point raised was the effect upon motors. In reply to that he would only say that he held the opinion, and always had held it, that motors were unfit for lighting circuits, especially alternating-current motors, with their large idle current. He prophesied that if motors became popular the electric light would become unpopular. It was impossible to regulate properly with alternating-current motors on the circuits. Having come now to the proposed method of reducing the alternator losses, viz., by halving the induction, he was glad to have Mr. Mordey's support as to the saving being an undoubted fact. At the same time, Mr. Mordey had misunderstood Diagram No. 7, the curves on which were drawn to show that the losses in alternators varied nearly with the square of the induction. The plotted experiments were made with an iron-cored alternator, but experiments with Mr. Mordey's own alternator would follow the same curves; indeed they would approximate more nearly to the true parabolas drawn, because the hysteresis loss peculiar to an iron-cored alternator did not vary quite as the square of the induction. The objection to Mr. Rider's suggestion of putting an alternator down for light load which had no iron in the armature was chiefly its first cost; they thought it important to save the first cost and space occupied by a special light load plant. Mr. Rider seemed to think that 3·4 H.P. was hardly worth saving—it was more than that—but even 3 H.P. or 4 H.P. for 16 hours a day for 365 days in the year cost an appreciable amount, and was certainly worth saving in a small station. Mr. Mordey said that it was possible to design his alternator to give on short circuit no more current than an iron-cored. Quite so—but what, then, became of the characteristic? It was possible also to design an iron-cored alternator with as good a characteristic as Mr. Mordey's—at a price. Mr. Nisbett thought that they had overlooked the losses in an injector due to condensation of steam. He thought Mr. Nisbett had hardly done justice to the remarks made under this heading in the Paper. They had given a great deal of consideration to the whole subject, and had come to the conclusion that nothing but careful and authoritative experiment could settle the point. They had looked up crowds of references, but had been unable to find any reliable results of experiments. He would ask Mr. Nisbett to reconsider the question, bearing in mind that all the heat in the steam went back into the boiler. Mr. Still had replied very fully to the criticisms of Thomson's law, but there was one point—Mr. Nisbett contended that if ¾d. per unit was taken as the cost of the energy consumed by the auxiliaries, that 1½d. ought not to be taken when considering the effect of the losses in the mains, but ¾d. The two problems were, however, entirely different. In the first instance the question to be settled was whether to drive the auxilliaries by the main engine. The main engine was running in any case, and therefore for the purposes of comparison, its standing losses would not be taken as chargeable against the auxilliaries, whereas the standing losses of a separate plant must be. That was surely good logic. But in the case of the losses in the mains the problem was different. There was no alternative to consider, and all losses as in meter shunt transformers, mains, &c., should be charged at the full works cost, including fuel, oil, wages, &c., based upon the output registered by the station, not the consumer's meters.

Mr. FAWCUS said that in rising to propose a vote of thanks to Mr. Cowan and Mr. Still for their Paper, he would just make only one remark about the steam pipes. He was rather surprised to hear Mr. Rider and Mr. Hesketh tell them that they could not keep their steam pipes tight, and he pointed out that there were thousands of plants where the steam was shut off every day. If electrical engineers could not do what steam engineers could, they had better learn.

A METHOD OF MEASURING THE LOSS OF ENERGY IN HYSTERESIS.*

BY G. F. SEARLE, M.A.

The extensive employment of transformers in the distribution of energy by alternating electric currents has caused the measurement of hysteresis in iron to become a matter of such commercial importance as to stimulate efforts to find a means for readily testing iron as to its quality with respect to hysteresis. The subject is important not only commercially but also from the purely scientific point of view, for it can hardly be doubted that our knowledge of the molecular structure of iron would receive some extension if a means were provided by which the effects of various physical conditions—stress, temperature, the passage of electric currents, &c.—upon the loss of energy in hysteresis could be investigated with a comparatively small expenditure of time.

As is well known, the loss of energy occasioned by any cyclic change in the magnetisation of iron is equal to $\int \mathrm{H}\,d\,\mathrm{I}$ in ergs per cubic centimetre of iron per complete cycle, H denoting the magnetic force and I the intensity of magnetisation, both in C.G.S. units. The waste of energy, $\int \mathrm{H}\,d\,\mathrm{I}$, I shall denote by W. The value of $\int \mathrm{H}\,d\,\mathrm{I}$ may be obtained by plotting in a curve the simultaneous values of H and I from a numerous series of observations, and then measuring the area of the curve. Or again, since, if B is the magnetic induction, we have $\mathrm{B}=\mathrm{H}+4\pi\,\mathrm{I}$, so that

$$\mathrm{W}=\int \mathrm{H}\,d\,\mathrm{I}=\frac{1}{4\pi}\int \mathrm{H}\,d\,\mathrm{B} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

(for $\int \mathrm{H}\,d\,\mathrm{H}$ vanishes when applied to a cyclic change), it follows that the hysteresis loss may be determined by plotting and measuring the curve given by simultaneous values of B and H. To obtain any satisfactory curve at least a dozen simultaneous observations of H and B are needed.

I have striven to design a method which should enable the hysteresis loss to be determined by a single observation of the "throw" of a spot of light along a scale. The method was far from being perfected when this communication was made to the Society on November 11, 1895, but it has been represented to me that though at present imperfect it is of sufficient interest and promise to justify its finding a place in the Society's pages.

A bar of iron of cross-section A is placed in a solenoid wound with N turns of wire per centimetre of its length. The current C which flows round the solenoid and magnetises the iron, also passes round the fixed coils of a sensitive electrodynamometer. A secondary coil of n turns is wound over the iron, and is connected in series with the suspended coil of the electrodynamometer, the resistance of the secondary circuit being R. When the primary current C changes, the magnetic induction B changes, and an E.M.F. $A\,n\,d\,\mathrm{B}/d\,t$ is set up in the secondary circuit. If the time-constant of the secondary circuit is very small compared with the time of a complete cycle, the effects of self-induction may be neglected, and then there is a current γ in the secondary circuit of amount $\gamma=\frac{\mathrm{A}\,n}{\mathrm{R}}\frac{d\,\mathrm{B}}{d\,t}$. Now the relation between C and H is expressed by $\mathrm{H}=4\pi\,\mathrm{N}\,\mathrm{C}$, so that $\mathrm{C}=\mathrm{H}/4\pi\,\mathrm{N}$. Hence, if the couple experienced by the suspended coil when a current i_1 flows in it and a current i_2 flows in the fixed coil is $q\,i_1\,i_2$ ergs, the couple experienced by the suspended coil at any instant due to c and γ is $q\,c\,\gamma$ ergs, supposing that the deflection is not so large that the value of q is appreciably different to its value in the equilibrium position.

Now, if the time of vibration of the moving coil is so great compared with the time occupied by the double reversal of the current that this process may be regarded as completed before the coil has moved sensibly from its equilibrium position, the angular momentum acquired by the coil for a single double reversal of the primary current is

$$\mathrm{K}\omega=\int q\,\mathrm{C}\,\gamma\,d\,t=\frac{q\,\mathrm{A}\,n}{4\pi\,\mathrm{N}\,\mathrm{R}}\int \mathrm{H}\frac{d\,\mathrm{B}}{d\,t}d\,t=\frac{q\,\mathrm{A}\,n}{4\pi\,\mathrm{N}\,\mathrm{R}}\int \mathrm{H}\,d\,\mathrm{B}, \quad . \quad (2)$$

where K is the moment of inertia of the coil and ω its initial angular velocity. Thus, since $\int \mathrm{H}\,d\,\mathrm{B}=4\pi\,\mathrm{W}$, we have

$$\mathrm{W}=\frac{\mathrm{N}\,\mathrm{R}}{q\,\mathrm{A}\,n}\,\mathrm{K}\omega \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

* Paper read before the Cambridge Philosophical Society.

Digitized by Google

Let T be the time of the complete vibration of the coil, θ it greatest angular displacement or "throw" and η the restoring couple exerted by the suspension per radian of displacement. We have, by the conservation of energy,

Initial kinetic energy = Potential energy at extremity of swing, so that

$$\tfrac{1}{2} K \omega^2 = \tfrac{1}{2} \eta \theta^2. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Also

$$T = 2\pi \sqrt{\frac{A}{\eta}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

From (4) and (5) we find

$$K\omega = \frac{\eta \theta T}{2\pi}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Thus from (3) we have

$$W = \frac{N R \eta T}{2\pi q A n} \theta. \quad . \quad . \quad . \quad . \quad . \quad (7)$$

The quantity η/q is easily determined as follows:—

Let currents i_1, i_2 flow in the suspended and the fixed coils of the electrodynamometer respectively, and let ϕ be the observed steady deflection, then

$$q\, i_1 i_2 = \text{couple} = \eta \phi, \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

so that

$$\eta/q = i_1 i_2/\phi.$$

If there is any appreciable damping, the expression must be multiplied by $1+\frac{1}{2}\lambda$, where λ is the logarithmic decrement. We have, finally,

$$W = \frac{N R T i_1 i_2}{2\pi A n \phi} . \theta (1+\tfrac{1}{2}\lambda). \quad . \quad . \quad . \quad . \quad (9)$$

Thus the "throw" of the coil is proportional to the energy lost in hysteresis.

It is evident that this affords a very ready means of testing the hysteresis of iron under different physical conditions for a given maximum value of H, the magnetic force, for all that has to be done after the constant of the instrument has once been determined is to observe (by means of a mirror and lamp and scale) the throw produced by a single double reversal of the magnetising current. For instance, a steady electric current may be maintained through the iron, and the value of W for each value of this current may be determined by simple observation of the "throw" in each case. If it is desired to investigate these effects for a given maximum value of B, the magnetic induction, the process is a little more complicated, because the value of B has to be found by the ballistic galvanometer method, and the strength of the magnetising current so adjusted on each occasion that the value of B may be kept constant under the varying conditions imposed upon the iron.

In the electrodynamometer which I have constructed for this experiment, the suspended coil is a long narrow coil of 120 turns, about 8cm. long and 1·5cm. wide, suspended by a silver wire $\frac{1}{1000}$in. in diameter. The fixed coils have 500 turns and are designed so as to fit closely round the suspended coil. With 1,285 turns in the secondary coil and with the resistance in the secondary circuit about 100 ohms, the instrument is sensitive enough to measure the hysteresis loss in the case of iron wire 0·02 sq. cm. in cross-section. I have made the instrument sufficiently sensitive to measure W for so thin a wire with a view of investigating the effects of tensile and torsional stress upon the hysteresis.

Up to the present (December 3, 1895) I have not been able to make any accurate determinations, owing to the fact that I have so far used an ordinary rocking mercury key for reversing the primary current. With this key, on breaking contact, the primary current is stopped very quickly, and when contact is re-established, the current very quickly rises to its full strength, and each of these changes takes place in a time not very large compared with the time-constant of the secondary circuit. On account of this the instrument has given results about 100 per cent. too large, as judged by the value of W obtained by a B-H cycle. When, however, a coil with a large coefficient of self-induction was inserted in the primary circuit, so that in spite of the key the primary current could not vary rapidly, the discrepancy was reduced to about 5 per cent. But I have designed a key (somewhat after the fashion of Prof. Ewing's "Sine Function" key) which will allow the current to be quite gradually reversed, and some preliminary observations have led me to expect that with this key the instrument may work quite satisfactorily.

Note added December 18, 1895:—The following method of determining the constant of the instrument is much more convenient than that described in the Paper. Let a constant current, C', flow in the primary circuit, and while this current is flowing suddenly produce a known charge, P, in the number of lines of magnetic force passing through the secondary circuit. This is conveniently done by suddenly inverting an "earth inductor" which has been placed in the secondary circuit. The time-integral of the current thereby produced in the secondary circuit is P/R, and thus the initial angular momentum of the suspended coil is

$$K\omega' = \frac{q C' P}{R}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

where ω' is the initial angular velocity.

But, if θ' is the "throw" produced, we have by (6) $\omega/\omega' = \theta/\theta'$, so that by (3) and (10)

$$W = \frac{C' P N \theta}{A n \theta'}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

Two determinations of $C' P N/A n \theta'$ on two different days agreed to within 0·5 per cent.

The reversing key mentioned in the Paper has been constructed, and measurements of the hysteresis for a specimen of steel wire have given results agreeing, within the limits of accuracy of the observations, with the values obtained by B-H cycles. For very soft iron in which the maximum value of $d\,B/d\,H$ is over 8,000, and six times its average value, there is still a difficulty due to self-induction when a single wire about 0·01 sq. cm. is tested. But I hope to overcome this difficulty shortly.

PHYSICAL SOCIETY.

At an ordinary meeting of the Physical Society held on March 27, 1896, Prof. Carey-Foster, Vice-President, in the chair, Prof. J. A. Fleming read a Paper on

"The Edison Effect."

The Edison effect alluded to in the title of the Paper is that if a metal plate is placed inside the loop of an incandescent lamp, then a galvanometer, of which one terminal is connected to this metal plate and the other to the positive leg of the lamp, will indicate a current passing from the leg to the plate. If, however, the galvanometer is connected to the plate and the negative leg no current passes.

Prof. Fleming, by connecting the poles of a condenser (1) to the two legs, (2) to the plate and positive leg, and (3) to the plate and negative leg, and in each case discharging the condenser through a galvanometer, has shown that after the lapse of a certain time, depending on the position of the plate, if the lamp is working at about 4 watts per candle, the potential of the plate falls to that of the negative leg. If the plate, instead of being inside the loop of the filament, is outside, then the time taken by the plate to acquire the potential of the negative leg is considerably longer.

The space between the plate and the negative leg exhibits a kind of unilateral conductivity, for a battery having a low voltage is able to send a current from the plate to the negative leg, but not in the opposite direction. If, instead of using a cold metal plate, a second filament, maintained in a state of incandescence by an insulated battery, is used, then a current can be obtained between this filament and both the positive and negative legs.

If the voltage on the lamp is raised considerably above that required to give 1 c.p. for 4 watts, then a current can be passed from the plate to the negative leg, while a galvanometer connected to the positive leg and the plate will indicate the passage of a current from the positive leg to the plate. When the lamp is in this condition the space between the plate and the negative leg is very sensitive to the effects of a transverse magnetic field, such a magnetic field causing a large increase in the resistance.

The curve showing the connection between the current passing from the positive leg to the plate and the volts between the terminals of the lamp is found to be discontinuous. As the volts are raised the current suddenly increases about tenfold, and it is while the lamp is in the condition corresponding to this upper portion of the curve that it is sensitive to the influence of the transverse magnetic field.

By using a movable plate it has been found that the minimum current is obtained when the plate is nearer the positive then the negative leg.

When an alternating current is used to supply the lamp, a continuous current can be obtained passing from the plate to either of the legs.

If a small platinum cylinder is placed surrounding each of the legs, then a current can be obtained between the cylinder and the positive leg, but no current between the two cylinders. The largest effect occurs when a cylinder near the end of the negative leg is connected to the positive leg. The author considers that his experiments show that the resistance of a vacuum tube to the passage of a discharge would be greatly reduced if the cathode is made incandescent.

Prof. S. P. THOMPSON said he would like to have some information as to the state of exhaustion of the lamps; whether this was such as is found in ordinary commercial lamps or whether it more nearly approached that used by Crookes. A great change in the conductivity, &c., took place at an exhaustion slightly greater than that ordinarily found in incandescent lamps. It would be of interest to vary the size of the cathode and to investigate whether the magnitude of the effects observed depended on the fall of potential per unit length along the filament. Another point was whether the position of the plate for which the effect was a minimum was the same for all lamps, or whether it changed with the volts and the length of the filament employed. Again, did the minimum occur at a certain

Digitized by Google

fraction of the distance between the positive and negative legs or, as was the case in some of the phenomena observed by Crookes, at a definite distance from either of the legs. These points might be investigated by means of a lamp with a straight filament, where the fall of potential per unit length along the filament might be the same as with the loop-shaped filament, but the fall of potential per unit length in the vacuum would be different. The author's proposed experiment of heating the cathode by concentrating on it the rays of a lamp did not seem to him (Prof. Thompson) to differ materially from Crookes' experiment in which an incandescent wire heated by a current was used as the cathode.

Mr. SKINNER said that the heating of the cathode by means of a "burning-glass" could easily be carried out.

Mr. BLAKESLEY pointed out that it would be quite possible to produce an increase of the current by means of a magnet.

Mr. SERLE said that Prof. J. J. Thomson had shown that a magnet affected the conductivity of a gas.

Prof. FLEMING, in his reply, said that no doubt the effects were largely dependent on the vacuum in the lamps. The lamps employed were exhausted to the ordinary commercial vacuum. Since it was found that the "treating" was more worn off the negative leg of the filament, and that a screen placed between the legs of the filament was more blackened on the side turned towards the negative leg, it would appear that the particles of carbon were shot off from the negative leg, and hence perhaps the charge was carried by these carbon molecules.

A Paper of a purely mathematical character, entitled "**Notes on the Electro-Magnetic Effect of Moving Charges,**" by Mr. W. E. MORTON was read by Mr. SERLE, who also made some remarks on his own investigations dealing with this subject. The Society then adjourned till April 24th.

CORRESPONDENCE.

THE ATKINSON REGULATING TRANSFORMER.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of April 3rd is published an interesting Paper by Messrs. Cowan and Still on "The Regulation of Pressure and the Reduction of Light Load Losses in Alternating Current Systems of Electric Supply." For the purpose of regulating the feeder pressures the authors describe the use of a regulating transformer, illustrated in Fig. 3 VI. and Figs. 4 and 4A. The authors give what purports to be an historical sketch of the genesis of this class of regulator, and show the advantages possessed by the type adopted by them, but omit to mention that the type of regulating transformer made by them was patented by the present writer in 1888 (No. 16 852), and a regulator of this class was first made by the author's then firm (Messrs. W. T. Goolden and Co.) in that year. The oversight is the more curious in that the Manchester Edison-Swan Company (Limited) have arranged to make these transformers under licence from the present owners of the patent, Messrs. Easton, Anderson and Goolden (Limited).—Yours &c.,

April 7, 1896. LLEWELYN B. ATKINSON.

Arc Spectra.—In the current number of the *Physical Review* Miss C. W. Baldwin describes some of her photographic researches in the spectra of different parts of the carbon arc, and in the effect upon these spectra of various alkalies introduced into the arc. Miss Baldwin was led to undertake these researches by the discovery by Prof. B. W. Snow that the curves of bolometric measurements of the carbon arc were materially changed by the introduction of the alkali metals. For example, while in the ordinary arc he had several very strong maxima in the ultra-violet and in the visible spectrum, he discovered that upon introducing the metals these intense regions disappeared, and strong maxima were now observed only in the infra-red. Miss Baldwin finds that many of the metallic lines are stronger nearer the negative carbon, and are weak or invisible at the positive carbon, while in others the brightness is uniform throughout, and in still others the brightness is a maximum in the outer sheath of the arc. These several characteristics are sometimes all noticeable in the lines of the same element. For example, in the calcium spectrum all the triplets of the second series of Kayser and Runge are strongest in the centre, while $\lambda = 3968\,63$ and $\lambda = 3737\cdot08$ and their companions, as well as certain other lines, are much stronger in the yellow part of the arc flame. Miss Baldwin appears to have exhaustively mapped the lines of the various parts of the arc spectrum.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d. abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many origin illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables. 30s., post free.

"COMPREHENSIVE INTERNATIONAL WIRE TABLES FOR ELECTRIC CONDUCTORS."—By W. S. Boult, price 5s., post free.

TENDERS INVITED.—The Corporation of Sunderland are prepared to receive tenders for an evaporative tubular surface condenser, with air and circulating pumps. Specifications, &c., may be obtained at the office of the borough electrical engineer (Mr. C. S. Vesey Brown) at the electric supply station, Dunning-street, and tenders addressed to the Town Clerk (Mr. Fras. M. Bowey), Town Hall, must be in by 5 p.m. on Wednesday, the 29th inst. Our advertisement columns contain further particulars.

——— The Vestry of St. John, Hampstead, invite tenders for the supply, delivery and erection at the Central Station, Stoneyard, Lithos-road, Finchley-road, N.W., of a steam alternator, switchboard, steam and exhaust pipes, feed water heater, tank, and appurtenances, and these can be tendered for either as a whole or in part. The specification, &c., may be obtained after the 11th inst., at the offices of Mr. Arthur P. Johnson, Vestry Hall, Hampstead, to whom tenders must be sent not later than 4 p.m. of the 27th inst. Further particulars are given in our advertisement columns.

——— The Public Lighting Improvement Committee of St Helier, Jersey, invite communications from persons wishing to establish a lighting station in that town for the supply of electric, gas, or other forms of light for both public and private purposes. Communications should be sent to Mr. P. Baudains, Ecr. Constable, Town Hall, St. Helier, Jersey. Some further essential parti-

Digitized by Google

culars will be found in our advertisement columns, and other information can be obtained on application to the Town Hall.

TENDERS INVITED.—The Bedford Urban Sanitary Authority invite tenders for the supply and delivery of vulcanised rubber cables. Tenders must be sent in to the Clerk, Mr. T. S. Potter, Town Hall, Bedford, by Tuesday, the 21st inst. Some further particulars appear in our advertisement columns.

——— The Commissioners of the township of Rathmines and Rathgar, Ireland, require tenders for the electric lighting of the new Town Hall and offices, for which about 250 lights with the necessary generating plant will be required; also for an installation of telephones and electric bells. Tenders to Mr. F. P. Fawcett, Town Hall, Rathmines, by 10 a.m. of Monday, the 20th inst.

——— The General Direction of the Roumanian Posts and Telegraphs require tenders for the supply of 60,000 porcelain insulators and 10,000 porcelain "buttons." Tenders, addressed to the Direction at Bucharest, must be in by the 18th inst.

——— The Harrogate Corporation require tenders for steel roofs, girders, &c., for their electricity supply station. Tenders to the Borough Surveyor, Mr. S. Stead, by the 13th inst.

——— The Wakefield City Council invite tenders for the building work in connection with the construction and erection of a chimney shaft and foundations and an electricity supply station. Tenders to the Town Clerk by the 22nd inst.

——— The Bedford Urban Sanitary Authority require tenders for the construction of five underground electric sub-stations. Tenders to the Clerk, Mr. T. S. Porter, Town Hall, Bedford, by the 21st inst.

TENDERS ACCEPTED.—The St. Pancras Vestry have accepted the tender of Messrs. Crompton and Co. for the supply of additional plant at the King's-road electricity station, including three engines and dynamos, steam pipe connections, switchboard, &c., for £6,456. 17s. 10d.

——— The Gas and Electricity Committee of the Bradford Corporation have decided to recommend for acceptance the following tenders for the supply of plant required for the new electric supply works:—

Epstein Electric Accumulator Co.... .	Batteries.
Cole, Marchent and Morley	Surface condensing plant.
British Insulated Wire Company	Cables.
Joseph Booth and Bros.	Travelling crane.
John Spencer	Steam and exhaust pipes.

——— The Huddersfield Town Council have placed orders for the supply of additional plant for their electricity station as under:—Babcox and Wilcox (Limited), two boilers; Messrs. Meldrum Bros., forced-draught apparatus; and Messrs. R. Stephenson and Co., surface condenser.

——— The Brighton Town Council have accepted the tender of the Reason Manufacturing Company for the supply of 500 switches for the incandescent lamps for street lighting at £487. 10s. Four other tenders were received, and the figures varied from £368. 15s. to £806. 5s.

LIQUIDATIONS.—At a meeting on March 25th it was decided to wind up Morris Brothers, Limited (electrical instrument makers) voluntarily. Mr. E. J. Abbott, C.A., Birmingham, has been appointed liquidator.

——— Claims against Fossick and Co. (Limited), makers of dynamo castings, &c., must be sent in to the liquidator, Mr. E. Lucas, 145, Cannon-street, E.C., by May 16th.

——— A meeting will be held at Messrs. Pratt and Norton's, 9, Old Jewry-chambers, E.C., on May 5th, to receive an account of the winding up of the Arcas Plating Company (Limited).

APPOINTMENT.—Mr. W. H. Woodall, who was for some time in the City of London Electric Lighting Company's employ at their Bankside station, has been appointed to succeed Mr. W. Bathurst as assistant to Mr. G. Cottam at the Hampstead electricity station. Between 60 and 70 applications for the post were received.

CORRECTION.—Mr. H. J. Dowsing, whose commencing in business as electrical engineer and contractor we notified last week, desires us to say that his address is 24, Budge-row, Cannon-street, London, and not 14, as incorrectly given in our last issue, from particulars supplied to us by Mr. Dowsing.

DISSOLUTIONS.—The partnership between Frederick Charles Allsop and Charles William Treacher, electric lighting engineers and contractors, of 165, Queen Victoria-street, London, E.C., has been dissolved. Debts by Mr. C. W. Treacher.

PERSONAL.—Mr. Wm. H. Booth has, we are informed, resigned his appointment as managing engineer for Messrs. Le Grand and Sutcliff, and has taken offices at 17, Shaftesbury-avenue, London, W., where he will carry on business in steam engineering, water supply, and electrical transmission of power, &c.

AGENCY.—Messrs. Mavor and Coulson, of 57, West Nile-street, Glasgow, have appointed Mr. C. R. G. Smythe, of 12, Idol-lane, E.C., their London agent.

BANKRUPTCY.—A first and final dividend of 1s. 10½d. in the £ is payable in the bankruptcy of Philip C. Pope, electrical engineer, of Hapton, near Burnley, at the Official Receiver's, Preston, on the 17th inst.

SCHUCKERT AND CO.—It is stated that Messrs. Schuckert and Co., of Nuremburg, are about to establish branch works in Vienna.

"CASSIER'S MAGAZINE."—The contents of the April issue of this magazine include "Electric Metal Heating and Working," by Joseph Sachs; "An International Standard of Screw Threads," by Thomas Mudd; "Power from Town Refuse," by F. W. Brookman; "American *versus* European Shop Practice," by Robert Grimshaw; and "The Evolution of the Horseless Carriage," by B. F. Spalding. The number also contains articles on "Sugar-Making Machinery in Cuba," "Floating Cranes and Derricks in Italy," "The Automatic Weighing Machine," "Power for a Modern Paper Pulp Mill," and "A Concrete Engine Foundation Block."

ABERDEEN.—The gas manager (Mr. A. Smith) and the electrical engineer (Mr. A. S. Blackman) have prepared a joint report on the extension of the electricity works. The report states that the capacity of the plant at the station is an equivalent of 8,400 8 c.p. lamps, but when the unit of plant on order is added they would be able to supply 11,600 lamps, and it is anticipated that by October next this number will have been applied for. Consequently they recommend that the buildings and plant be extended at an estimated cost of £10,000, and that various extensions of the mains be made at a cost of £9,500. Should the Council decide to carry out these extensions, the capacity of the station will be increased to an equivalent of 16,500 8 c.p. lamps, and, in addition, an adequate reserve will be provided.

"A GREAT TRAMWAYS SCHEME."—The *Pall Mall Gazette* is responsible for a wild statement "that a scheme is on foot which, if adopted, will revolutionise the tramway service of London and outlying districts. A powerful syndicate, consisting of tramway experts and financiers, has offered to take a lease of the existing lines from the County Council in order to consolidate the whole service, to make extensions and experiments, to apply mechanical traction throughout, and to offer the public greatly increased travelling facilities." So far the particulars given by our contemporary are as vague as anything even in an evening journal can very well be.

ASHTON-UNDER-LYNE.—On the recommendation of the Electric Lighting Committee, the Town Council have decided to appoint Mr. S. V. Clirehugh consulting electrical engineer.

BANGOR.—Lord Penrhyn is considering the question of lighting Penrhyn Castle electrically, and has applied to the Bangor City Council for the terms on which electric current would be supplied. At the last meeting of the Council it was decided, subject to certain conditions, to lay an electric light main to the Castle. Subsequently, the tenders recently invited for contracts Nos. 2 and 3 were opened, and were ordered to be submitted to the Electrical Engineer (Mr. F. H. Medhurst) for analysis and report.

BELFAST.—At the last meeting of the City Council the minutes of the Council in Committee stated that a system of electric traction would be of advantage to the city if an arrangement could be come to with the Tramways Company, and recommended that a committee be appointed to meet the Directors of the Company and report. The report of the Electrical Committee stated that, without making allowance for interest or sinking fund, there had been a profit of £385 on the electricity works for the past year. The minutes and report were, after discussion, approved.

BOLTON.—At the last meeting of the Town Council, on the motion for the approval of the minutes of the Gas, Electricity and Street Lighting Committee, a long and interesting debate took place on the question of the resignation of the borough electrical engineer, Mr. J. H. Rider. The electricity and gas works are in the hands of the Council, and one committee manages both departments. Mr. Councillor Proctor opened the discussion by expressing his regret at the absence of the chairman of the Committee. He regarded with considerable alarm the changing of their electrical engineer at this particular juncture, and said it must be a source of regret to every member of the Council that a gentleman who had served them so faithfully and so well was about to leave them. He strongly protested against the action of the Committee in refusing the electrical engineer's application for an increase of salary, while they proposed to pay his successor the very sum demanded by Mr. Rider. He thought therefore that an honorarium or something in the nature of an expression of regret at his departure should be presented to Mr. Rider. In the discussion which ensued, nearly every speaker testified to Mr. Rider's ability, and expressed regret at losing his services. The minutes were, however, passed by 23 votes to 16.

Digitized by Google

BRIGHTON.—Electric light extensions are evidently the order of the day at Brighton. At the last meeting of the Town Council, the Lighting Committee submitted a report by the electrical engineer (Mr. Arthur Wright) with reference to borrowing additional money for electric light extension purposes. Mr. Wright gave figures showing the constant and rapid increase in the demand for current, and stated that it appeared likely that this rate of increase would be maintained. In 1894 the department sold 78,000 units, in 1895, 148,000, and in 1896, 228,000. These figures conclusively proved the soundness of the policy of constantly extending the mains, in arranging the tariff so as to enable small householders to avail themselves of the advantages of the electric light, and in gradually increasing the size and capacity of the generating station. Mr. Wright claimed that the cost of generating current in Brighton during the past year, exclusive of coal, was lower than that of any other town whose accounts had yet been published. £27,500 was now required for house connections, meters, extensions of mains, &c., and for additional plant in the supply station. The Committee recommended that application be made to the Local Government Board for sanction to borrow £23,000 on the Electricity Works Account for 25 years, and £4,500 on the District Fund Account for 15 years. Councillor Stafford, in moving the adoption of Mr. Wright's report, said it was so clear and comprehensive that it required very little explanation from him. The motion was seconded and carried unanimously.

CHELTENHAM.—On Friday, the 27th ult., Major-General H. D. Crozier, R.E., held an inquiry at Cheltenham into the application of the Town Council for the sanction of the Local Government Board for two further electric lighting loans amounting to £25,000. The present rateable value of the borough is £259,126, and the outstanding loans under the Sanitary Acts amount to £117,780. In the course of his observations, the Town Clerk said he did not know whether it was necessary to say anything as to the length of time over which the loan was to extend, but he hoped that the Local Government Board would give them 30 years. The Inspector remarked that the Local Government Board would do nothing of the kind, 25 years was the period now fixed for electric light loans. Alderman Norman stated that there were at present 6,200 8 c.p. lamps connected, and 700 lamps were waiting to be connected. The Inspector asked if all the extensions estimated in the £10,000 loan were within the authorised area of supply. It was stated in reply that they were, with one exception, which was an extension which had been made with the authority of the County Council to a residence taking 600 lights. The Town Clerk explained that he was aware that the Town Council had no legal power to do this, but that they did not ask the Local Government Board for any money in this connection, the outlay having been charged to revenue. General Babbage, as a ratepayer and owner, offered considerable opposition to the loan, his point apparently being that the Corporation should confine its operations to the compulsory area for which they obtained the original loan of £16,000, and not proceed to lay mains in other sections of the town until the compulsory area had been filled up; when they showed a profit on that part of the undertaking he would offer no opposition to the raising of further capital. Opposition was also offered by Col. Graham, who stated that when the electric lighting scheme was first brought up the ratepayers were not in any way consulted about it. There was no towns-meeting, and the ward representatives had not consulted their constituents on the matter. The Town Council had recently proposed to purchase the gas undertaking, but a towns-meeting having been called, the scheme was decisively negatived, and he thought it possible that a similar result might have taken place had a towns-meeting been called in connection with the electric light undertaking. At the conclusion of the proceedings the Government Inspector proceeded to inspect the electric light station and network.

CHURCH LIGHTING.—The Catholic Apostolic Church, London-street, Edinburgh, has been wired and fitted up for the electric light. The installation consists of about 160 incandescents of 8 and 16 c.p., 75 being placed in the nave, 35 in the chancel and sanctuary, and the remainder in the sacristry, hall, &c. In the nave the lights have been fixed in groups of six on the east side of each pillar, and on each side, about 45ft. from the floor, and concealed by the capitals of the pillars, clusters of lamps have been placed so as to throw a strong light on the subject painting over the chancel arch. In the chancel a pendant of beaten ironwork has been suspended over the priests' stalls in each arch, and behind the great chancel arch, and concealed by it, a long ornamental brass rod is fitted with lamps which throw down light on the altar and baldacchino, showing up the mosaics, statues and delicate stone carving of the latter, as well as lighting up the gilding and colours of the decorated ceiling. In the sanctuary hidden lights have been introduced into the dome of the baldacchino to light the altar and bring into prominence the colours of the marbles; while behind the baldacchino lights are hung in order to counteract the shadow thrown by it on the circular wall of the apse. The installation has been successfully carried out by Messrs. Anderson and Munro.

COOLGARDIE, WESTRALIA.—The local electric supply company in this town have found it necessary to apply for an extension of time for the public lighting by electricity. The rush of population owing to the gold discoveries has led to such demands upon the limited railway capacities of the district as to cause a serious block in the goods traffic, and the delivery of machinery has been delayed. At the meeting of the Scottish Westralia (Limited) on Wednesday reference was made to the important electric power works now in process of construction for the Yilgarn and Coolgardie goldfields, of which the Scottish Westralia (Limited) is the sponsor. Lord Kelvin, whose opinion has been sought, has pronounced in favour of the undertaking, and in a report has expressed the opinion that the extensive scheme is thoroughly practical, and likely to prove highly remunerative.

COVENTRY.—At the last meeting of the Town Council the minutes of the Electric Light Committee stated that in order to keep pace with the demand for electric current it would be necessary to provide an additional 200-kilowatt alternator and engine, two boilers, transformers, and various other plant and apparatus, at an estimated cost of £8,900. The Committee further recommended that application be made to the Local Government Board for sanction to borrow £13,000 for electric lighting purposes. In moving the adoption of the minutes, Alderman Hill referred to the very satisfactory progress the electric light was making in the town, and stated that, although they only started to supply current in November last, there was at present an equivalent of 6,000 8 c.p. lamps connected. The Committee's recommendations were adopted.

DERBY.—On Wednesday last Major-General H. D. Crozier, R.E, held a Local Government Board inquiry at Derby into the application of the Town Council for sanction to borrow £13,185 for electric lighting purposes. The inspector took exception to certain items, viz., £419 for obtaining powers (which he said the Local Government Board would not entertain) and to an item for loss on capital in the early stages of the undertaking. The Town Clerk said this money was paid to put the station into proper working order, and Mr. Harris said it was really interest on capital while the works were in course of construction. The inspector then suggested that the Town Clerk should draw up some explanation for the Board, as it seemed to him a very doubtful item. The inspector also said that he had not previously met with an item for interest on capital, and he asked for details, which were given by the borough accountant, after which the inquiry was adjourned.

EALING.—The report of the Electric Lighting Committee presented at the last meeting of the District Council contained a recommendation that the electric light mains be extended to Gunnersbury, provided the residents agreed to pay interest on the capital outlay and a certain sum annually for depreciation, and also guaranteed that the receipts from the sale of current would amount to at least £50 a year. The recommendation was agreed to.

EDINBURGH.—The provisional estimates of the Electric Light Committee show an estimated expenditure of £20,435, and receipts amounting to £27,925, an estimated profit of £7,490. The Committee propose to reduce the price of current to 5d. per unit.

GRIMSBY.—Although the Town Council have lately had several discussions on the question of carrying out the terms of their Provisional Order (obtained in 1894), still they cannot be induced to make a move forward. Last week Mr. Curry moved that steps be at once taken to comply with the provisions of the Order, and that a sub-committee be appointed to collect information, but after a lengthy debate it was decided to again adjourn the matter for a month.

HALIFAX.—The Board of Guardians have decided to erect an infirmary at a cost of £130,000. In addition to a very complete electric lighting installation, it is intended to utilise electricity for working lifts, for heating purposes in the wards, kitchens, &c. Gas will only be employed for cooking. The Guardians have decided to put down an independent generating plant.

HAMMERSMITH (LONDON).—A letter has been received by the Vestry from Messrs. S. Z. de Ferranti (Limited), asking that consent to the Provisional Order of the London United Tramways Company should be conditional upon their agreeing to take electric current for working their trams from the Vestry's supply station. The letter has been referred to the Electrical Committee.

HELENSBURGH.—At the last meeting of the Police Commission it was decided to form an Electric Lighting Committee.

LAMBETH (LONDON).—The Electric Light Committee presented a report, in which the Vestry is recommended to transfer its Provisional Electric Lighting Order to Messrs. Julius Sax and Co., who undertake to carry out the terms of the Order, to lay mains in all the streets of the compulsory area, and to maintain and supply electric current to 25 arc lamps free of charge. It is also proposed that the charge for current is not to exceed 6d. per unit. The Vestry are to have the option of purchasing the works at 21 years at 25 per cent. above the actual value of the undertaking. Messrs. Sax and Co. further agree to provide and erect a dust destructor plant, and to treat all the parish refuse at 1s. 6d. per ton.

Digitized by Google

The Committee's proposal has excited strong opposition, and meetings have been held to protest against the suggested transfer. At a meeting held in Brockwell Park on Friday, Alderman Hubbard, Mr. George Offor, and several other speakers delivered speeches, and denounced the proposed surrender of the Order, advocating a temporary arrangement with a company for the supply of current, which would leave the Vestry freedom of action in the future. A resolution to this effect was carried unanimously. At another meeting Mr. Barclay Heward (Chairman), Alderman Hubbard and other speakers supported resolutions condemning the proposed transfer, and pledging the ratepayers to return members at the forthcoming election who would oppose the recommendation of the Committee.

LINCOLN.—At the last meeting of the Town Council the minutes of the Special Lighting Committee stated that they had fully considered the report of Dr. J. Hopkinson on the electric lighting question, and had come to the conclusion that the supply of electric current should be kept in the Council's hands. The Committee, therefore, recommended that they be empowered to take the necessary steps to establish electricity works in the town. Mr. Alderman Page, in moving the confirmation of the minutes, said that from every point of view it was desirable that they should undertake the supply of electric current, and that the initial cost of an installation would not be more than £15,000. Various speakers advocated the introduction of the electric light; but Dr. Collier thought that they should combine the electric light and dust destructor schemes, and moved an amendment to this effect. The recommendation of the Committee was, however, adopted.

LONGTON.—The Sub-Committee recently appointed to consider the offer of the North Staffordshire Tramways Company to lease them the tram lines in the borough, and to equip electrically, and also to make some extensions to the present system, now recommend the Council to agree to the following amended terms of the Company:—(*a*) The lease to be for 21 years, (*b*) a rental of £200 per annum to be paid for the existing lines, (*c*) a further annual sum to be paid equal to 7 per cent. upon the total capital cost of the proposed extensions, (*d*) the Company to pay the cost of repairs and renewals, and in case of dispute a reference to arbitration to an engineer, to be appointed by the Board of Trade. The Committee further recommend that the application for a Provisional Order be proceeded with. At the last meeting of the Council both recommendations were agreed to.

LLANDUDNO.—Mr. A. H. Preece has presented a lenghty report on the question of the establishment of electricity works in this town. The capital expenditure of an electric lighting scheme is put at £20,500, but if the Council decide to proceed with the dust destructor scheme the total would be about £23,400. Mr. Preece also reported as to combining a system of electric tramways with the above schemes, and the additional capital expenditure required for the triple scheme, which it is stated would be a certain success, would be £4,600, or a total of £28,000. The estimated annual revenue from these undertakings is put at £4,680, and the upkeep (including interest, sinking fund, &c.) £4,245, leaving a profit of £435. At a special meeting of the Council on Tuesday last it was decided to adopt so much of the report as related to the establishment of electric light and refuse destructor works, and to apply to the Local Government Board for sanction to borrow £25,000 for carrying out the schemes.

MEXICAN TELEGRAPHS.—There are stated to be 44,500 kilometres (27,500 miles) of telegraph lines in Mexico, serving a population of 12,570,000.

MOTHERWELL.—At Tuesday's meeting of the Police Commissioners the Lighting Committee recommended the Commissioners to establish electricity supply works at an estimated cost of £8,500, but, on the motion of Commissioner Dunlop, it was decided not to proceed with the scheme at present.

PADDINGTON (LONDON).—The Vestry have referred to the Electric Lighting Committee the question of obtaining a reduction in the price of electric current supplied by the Metropolitan Company from 7d. to 6d. per unit.

PADSTOW (CORNWALL).—The recent installation of the electric light at Mevagissey seems to have had a stimulating effect on the Padstow District Council. At the last meeting of the Council the Vice-Chairman (Mr. J. Williams) called attention to the introduction of the electric light into Mevagissey, and urged the members to adopt a similar course. They would obtain a far better and cheaper light than they were obtaining at present. The necessary capital outlay would not be much more than £1,000, and if they supplied current for private lighting they could, he urged, even make a profit on the undertaking. The matter will be further considered at a meeting of the Lighting Committee.

PETERBOROUGH.—At a recent meeting of the Lighting Committee the engineer presented a report as to the annual outlay which the suggested electric lighting scheme would entail. The Committee decided to make another canvass of the residents in th compulsory area in order to ascertain the probable demand for current.

POTTERIES EXTENSION TRAMWAYS.—About a fortnight ago Major Marindin, R.E, held a Board of Trade inquiry into the objections lodged by the Newcastle-under-Lyne District Council to the application for a Provisional Order by the promoters of the Potteries Extension Electric Tramways. In his report Major Marindin states that the Council's objections to the laying of the tramway within the borough were well founded, and that the promoters had failed in their contention that the assent of the Council to the present scheme, and without any modifications of the Order, should be dispensed with. The scheme did not offer the advantages which Newcastle might fairly claim, inasmuch as it merely provided a route between Newcastle and Hanley, and did not offer any facility for communication between Newcastle and the districts surrounding it. He thought that the tramways asked for by the Town Council to Silverdale and Chesterton were essential, and that the line to Wolstanton should be undertaken if the tramway between the latter place and Burslem were constructed, as this would supply a want and provide a through route to Burslem and Goldenhill; but he did not think that a case had been made out for a tramway to Trent Vale. As the Council and a large majority of the ratepayers were in favour of the construction of tramways, he was of opinion that, subject to these modifications, the scheme should be sanctioned.

THE TELEPHONE IN WAR.—A Cairo telegram states that Lord Cromer, accompanied by his financial adviser, proceeded on Tuesday to the War Office at Cairo at 10 o'clock in the morning, and remained until noon, conversing by means of the telephone with Gen. Kitchener, in charge at Wady Halfa, and was thus able to convey important instructions to the scene of operations.

TIGHNABRUAICH (ARGYLESHIRE).—This village can now boast of being up-to-date in its method of street illumination, for on Saturday last the residents celebrated the inauguration of the electric light. The cost of the installation has been generously defrayed by Mr. Samuel Millar, a local magnate. Current is obtained from a dynamo driven by an 8 H.P. oil engine. The contractors were Messrs. A. MacLellan and Co., of Glasgow.

WEST HAM.—At the last meeting of the Town Council the Highways Committee were instructed to submit the names of six electrical engineering firms who would be willing to supply and lay down the necessary plant and apparatus for the electric lighting of the borough.

WORKHOUSE LIGHTING.—The Portsea Island Board of Guardians have instructed Mr. Price, the superintendent of the Portsmouth Electric Light Works, to prepare specifications for wiring the centre block of the main workhouse building for the electric light.

WORKS LIGHTING.—The soap works of Messrs. Isdale and M'Callum, Paisley, are now lighted electrically. Current is supplied by an "Oldham" dynamo (60 amperes × 65 volts). The works and yard are illuminated by means of three 1,000 c.p. arcs, incandescents being employed for lighting the offices, &c. A complete system of telephones and electric bells has also been supplied by the contractors, Messrs. Robertson and Co., of Paisley.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fil. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

Willans and Robinson (Limited).

The ordinary half-yearly general meeting of this Company was held on Wednesday at Cannon-street Hotel, Mr. Mark Robinson, M.Inst.C.E. (Chairman) presiding.

The SECRETARY (Mr. C. S. Essex) read the notice calling the meeting.

The CHAIRMAN said: Gentlemen, again the Directors are able to address you in terms of congratulation. The business of our second year has surpassed that of the prosperous first year of the Company, though, to speak plainly, we did our best to restrict it, and now in the beginning of our third year the volume of our orders has burst all restrictions, and has risen to figures which are nothing less than astonishing. When the report was written we could only say that in less than three months the orders had reached 22,300 H.P.; we can now say that in three months they actually reached 24 400, or some 28 per cent. more than in the whole 12 months of 1893—itself the record year up to that time. It was upon the figures of 1893, or rather upon those figures averaged with previous and less favourable years, that the sale from the old to the new Company was arranged, and the payment for the goodwill fixed, and you will bear with me while I express the pleasure of the Directors, who were responsible for the prospectus of the Company, at this brilliant fulfilment of the modest forecast of increasing business which they made to you, and at the proof now plainly given that the price you paid for the business was a moderate one. For not only does our business increase, but its profitableness increases too. 1895 compares well in every way with 1894. In 1894, if we had divided profits "up to the hilt," instead of carrying to reserve, we might have paid about 9$\frac{1}{2}$ per cent. upon the Ordinary share capital then paid up. In 1895 we might have divided about 12$\frac{1}{2}$ per cent. upon a larger Ordinary capital, and this in face of the fact that we have written off depreciation upon an almost lavish scale. Omitting the Thames Ditton freehold, which follows a practically uniform rule, the value of our plant and machinery and patents at the beginning of 1895, plus the additions to them during that year, was £60,600, and from this sum (although many of the additions would not rank for depreciation at all during the same year) we wrote off no less than £6,703, or between 11 and 12 per cent. on the total. Yet our plant and machinery are kept in first-class condition out of revenue, and our patents bear no value beyond the sums actually spent upon, or in connection with them. We have been not less prudent in other questions which involve valuing, and, therefore, you may take this earning of 12$\frac{1}{2}$ per cent. on the Ordinary capital for 1895 as very truly earned indeed—earned, too, upon a good deal of idle as well as upon productive capital. When the transition period is over, and the unproductive capital, and that capital which, in the form of debentures, we have soon to consider, are earning money for us in the new works, we have the fullest expectation of doing better still; but until we have actually tested the results of business carried on upon the larger scale, and, under the different, though we hope more favourable circumstances of the future, it would be unwise to depart in the smallest degree from our present prudent attitude, or to cede the claims of the reserve fund in favour of large dividends. It must not be assumed that the extraordinary influx of orders for the first quarter of this year is always to be maintained. It has been largely due to the fact that we were known to be full of orders, many of the public bodies and private companies which undertake electric lighting in this country pressed forward to get their orders placed with us for next winter, so that the first quarter really brought many orders which would normally have been given in the second quarter of the year. The explanation is in itself, however, a remarkable tribute to our position, and to the credit in which the Willans engine is held, and whatever discount we may make from the first quarter's figures, they undeniably show a magnificent accession of business. It has been the steady object of the Directors for some years past to promote a demand for the Willans engine in much larger sizes—so soon, that is, as we may be in a position to supply them. We are glad to say that among the recent orders is one for four engines of 1,100 H.P. each, to be made, of course, at Rugby. We have an engine of 750 H.P. on order, for electric lighting, for one of our municipal bodies, and two of 600 H.P. each for another. An engine of 750 H.P., and another of 700 H.P., are on order for driving mills on the Continent, while nearly 40 engines are on order of sizes from 300 H.P. up to 500 H.P. In fact, the average size of the engines ordered in the first quarter of 1896 was not less than 263 H.P. The development of the really large engine work waits, of course, the completion of the new works. Of the cost of the new works now being constructed, and of the plant required for them, it is still early to speak with exactness. If no substantial additions beyond those now decided on become necessary, we may expect the cost of land, buildings, fencing, tramways, drains, levelling, &c., to be about £50,000, in addition to £9,800, which had been spent up to the end of 1895. The plant required for the buildings, as now planned, including, of course, not only machine tools, but such plant as engines and boilers, electric lighting and power plant, shafting and pulleys, cranes and overhead travellers, rolling stock and fire appliances, will probably cost us fully £30,000, beyond what had been spent up to December last, and including an allowance for various things which it is not desired to order until we are actually at work at Rugby. The two sums added together make £80,000 still to be spent, but it is evidently necessary to allow a margin beyond this. With regard to the question of new capital, the sum the Directors propose to borrow is £75,000, which is one-third of the present paid-up capital. The Articles of Association permit borrowing up to the limit of one-half of the paid-up capital, but we have to consider the views of borrowers as well as our own powers, and the Directors are not at present disposed to recommend an issue of more than £75,000, to form part of an issue which may be increased later to £100,000 subject to an undertaking to form one of the

Digitized by Google

conditions of the issue that the total issue shall at no time exceed one-third of the paid-up capital, whatever the latter may be, and shall never, of course, exceed £100,000. In the event of our business undergoing in the future any such startling expansion as its past history gives some ground for treating as possible, we have powers to issue £75,000 more share capital, and after that a further £35,000 could be borrowed, and this would raise the debenture debt to the proposed limit of £100,000. The authority to borrow up to £112,500 in all, proposed in the resolution, is necessary in order to give power to the Directors to obtain small loans (as from the Company's bankers) in the ordinary course of business. They have authority now, under Article 57, to borrow up to one-tenth of the paid-up capital, but this authority is, so to say, swallowed up in the debenture debt. When created it is necessary to provide by the resolution a margin of a few thousand pounds between the limit of the debenture debt and the limit of the total borrowing. This is why the resolution asks for a limit in excess of that which the Directors contemplate for the debenture debt. Allusion has been made to the Niclausse boiler. The delay in making it upon a large scale is not wholly an evil; it has enabled us to test it by extended use in various places before pressing it upon public acceptance. It has borne all tests most admirably. One electric lighting company which lately had two large boilers from us, has ordered three more, and quite enough are on order elsewhere to afford a most thorough trial. Arrangements have been made with the Admiralty for the manufacture of a set of Nic'ausse boilers for a fast boat, under royalty, by Messrs. Humphrys and Tennant, and the same eminent firm are also making other Niclausse boilers under licence from us. So far as we can foresee, this business promises very well indeed. I now beg to move—

"*That the report and accounts for the half-year ended December 27th last, submitted to the meeting, be, and the same are hereby, received and adopted.*"

Mr. W. H. WILLCOX seconded the resolution.

Mr. PEACH asked when they might expect to get a quotation on the Stock Exchange.

Mr. PERCY HUNTER thought the travelling and legal expenses were rather high, and inquired the reason.

The CHAIRMAN, in reply, said their application for an official quotation was now before the Stock Exchange Committee, and they hoped to receive a favourable reply at an early date. As to the expenses, he thought they were not unreasonable in view of all the circumstances which he explained in detail.

The resolution was then unanimously carried.

The CHAIRMAN next moved—

"*That a dividend for the half-year ended December 27th last at the rate of 6 per cent. per annum on the capital paid up on the Preference shares, and at the rate of 7 per cent. per annum paid upon the Ordinary shares be and the same is hereby declared.*"

Mr. G. W. ANDERSON seconded, and it was agreed to.

Sir GILBERT A. CLAYTON-EAST, Bart., moved—

"*That the Directors be, and they are hereby, authorised to borrow, for the purposes of the Company, any sum or sums of money not exceeding £112,500, to bear interest at such rate, to be secured in such manner, and to be issued on such terms as the Directors may determine.*"

He said that the idea of the Board was that the loan should take the form of Debenture stock, and that the amount should be £75,000, that the interest should not exceed 4½ per cent.; that the terms should be for a fairly long period, with the option of paying off earlier after 10 years, at a slight premium.

Mr. G. W. ANDERSON seconded the resolution, and it was carried *nem. con.*

The auditors (Messrs. Cooper Bros. and Co.) having been re-elected the proceedings terminated with a vote of thanks to the Chairman.

NEW COMPANIES, STATUTORY RETURNS, &c.

ERNEST F. MOY (LIMITED).—This Company was registered on March 20th, with a nominal capital of £5,000, in £1 shares, to acquire the business of a manufacturing electrical engineer and contractor, now carried on by Ernest F. Moy at Camden Town, London, N.W., and to carry on the business of manufacturing electrical engineers and contractors, electrical and mechanical engineers, founders, metal workers, electricians, suppliers of electricity, electrical apparatus manufacturers, &c. The first subscribers, with one share each, are: P. H. Bastie, electrical engineer; H. Gorton, electrical engineer; F. B. Gardiner, electrical engineer; H. Barton, engineer; J. Dyer, E. Dyer and C. G. Box.

NEW GENERAL TRACTION COMPANY (LIMITED).—This Company has entered into an agreement with Mr. Edwin A. King, of Winchester House, E.C., for the acquisition of a certain business, £15,000 fully-paid debentures in the Coventry Electric Tramways (Limited), the benefit of agreements with Messrs. W. Graff Baker and A. de Turckheim, with the said Coventry Company, with Messrs. W. Lowcock and G. Hill and with the Electric and General Contract Corporation (Limited), and also the benefit of tenders for the electrical equipment of tramways in Leeds and Glasgow, in consideration of the sum of £140,000, payable by the allotment of 4,000 Six per Cent. Cumulative Preference and 24,000 Ordinary shares of £5 each.

PERU TELEPHONE COMPANY (LIMITED).—The annual return to January 14th has been filed. Only seven shares have been taken up out of a capital of £100,000, in £5 shares, and no calls have been made.

QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).—The annual return to March 6th has been filed. The whole nominal capital of £60,000, in 3,000 Preference and 3,000 Ordinary shares of £10 each, has been taken up and issued as fully paid.

RUGBY SCHOOL ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to March 2nd, has been filed. The nominal capital is £5,500, in £50 shares; 70 of these have been taken up, and calls amounting to £45 per share made.

CITY NOTES.

APOSTOLOFF AUTOMATIC TELEPHONE PARENT SYNDICATE (LIMITED). At a meeting of the proprietors of this Syndicate on Wednesday last, it was decided to convert the £1 shares into 40 shares of 6d. each.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended April 5th were £815, against £935 in the corresponding week of 1895, a decrease of £120. The total receipts for the half-year amount to £13,471, against £13,583 for the corresponding period of 1895, a decrease of £112.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of March were £3,123.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of March amounted to £81,135, against £70,470 in the corresponding period last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—In our advertisement columns will be found a list of the numbers of 409 Five per Cent. Australian Government Subsidy Debentures of £100 each, which were drawn by lot on the 1st inst., and will be paid off at par on July 1st next, at Messrs. Barclay, Bevan and Co.'s, 54, Lombard-street London, E.C.——The traffic receipts of the Company for the month of March amounted to £47,747, and to £40,942 in the corresponding period of 1895.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of March amounted to £22,400. The total receipts from January 1st to March 31st were £66,800, against £68,000 and £63,000 in the corresponding months of 1895 and 1894.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 5th inst. amounted to £1,256. The amount for the corresponding week last year was £1,024. Increase £232.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY (LIMITED).—The transfer books of this Company will be closed from the 13th to the 22nd inst. inclusive.

SUBMARINE CABLES TRUST.—Notice is given that on and after the 15th inst. the sum of £2 on account of this Company's coupon, due 15th inst., will be paid by Messrs. Glyn, Mills and Co., 67, Lombard-street, London, E.C. Coupons should be left four clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended April 3rd, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,180.

WESTERN UNION TELEGRAPH COMPANY.—This Company have issued their report for the quarter ended March 31, 1896:—The following statement, dated March 11th, exhibits the condition of the Company at the close of the quarter ended December 31, 1895:—

Surplus October 1, 1895, as per last quarterly report...		$7,854,622 99
Net revenues, quarter ended December 31, 1895		1,603,416 25
		$9,458,039 24
From which deducting for—		
Dividend of 1¼ per cent. paid January 15	$1,191,948 75	
Interest on bonded debt	223,557 33	
Sinking funds	20,000 00	
	$1,435,506 08	
Left a surplus January 1, 1896		$8,022,533 16
The net revenues of the quarter ending March 31st, based upon nearly completed returns for January, partial returns for February, and estimating the business for March, will be about		1,250,000 00
		$9,272,533 16
From which appropriating for—		
Interest on bonds	$223,560 00	
Sinking funds	20,000 00	
		243,560 00
		$9,028,973 16
It requires for a dividend of 1¼ per cent. on capital stock issued, about		1,191,950 00
Deducting which leaves a surplus, after paying dividend, of		$7,837,023 16

In view of the preceding statements, the Committee recommend that a dividend of 1¼ per cent. on the capital stock of the Company be declared, payable on and after the 15th instant.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended March 31st are £3,162, against £2,757 in the corresponding period of 1895.

WESTINGHOUSE ELECTRIC COMPANY.—It is stated that the Directors of this Company propose to increase its capital by $5,000,000, and it is further stated that the agreement between the Company and the General Electric Company has been signed. The new scale of prices will be issued next week.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 935. [No. 25. Vol. XXXVI.] FRIDAY, APRIL 17, 1896. PRICE SIXPENCE.

NOTES.

Mr. HANBURY's remarks on the telephone service, in the discussion on Post Office estimates last week, were singularly devoid of all encouragement to Local Authorities desirous of working the town exchanges under municipal control. The subject was too large for us to do more than barely refer to it in our last Friday's leader; but unless the wishes of the large municipal bodies have materially altered within the past twelvemonth, their backwardness in Parliament is a little strange. If, however, they are still of the same mind, they could probably have what they desire by purchasing the plant and rights of the company outright, instead of setting up a competitive service, a course which it does not appear as if the present POSTMASTER-GENERAL would approve of except under conditions which are not likely to arise. To the acquisition by purchase, on the other hand, he would offer probably no opposition, for if that course were adopted by any considerable number of towns, the Post Office and the Government would be relieved of a grave embarrassment in the not very distant future. For somewhat similar reasons the National Telephone Company might not be unwilling to part gradually with rights which, sooner or later, it may be otherwise deprived of in a wholesale manner and on less favourable terms.

WHAT the terms of purchase by Local Authorities ought to be need not now be discussed. With the Post Office as an intermediary, they would no doubt be fair to both parties. That the telephone exchanges in any given area must be under exclusive control of one body is an axiom; and to attempt to create a new system for the mere purpose of superseding an existing one would be a wasteful proceeding, except where the existing system was hopelessly bad. We are not enamoured with the idea of municipal control, although there is a good deal to be said for it under present circumstances in relation to the telephone service. But where the Local Authorities are seriously dissatisfied with the present state of things, we would suggest that they inquire into the merits of purchase before irretrievably committing themselves to competition *à l'outrance*, or nothing.

IF the further progress of the electric lighting and electric traction industry were to be forthwith arrested, it would still have deserved well of the public. We will not to-day tackle that exceedingly thorny question, the relative merit and the relative cost of electricity and gas, nor go so far as to assert that the electric light, even as we now have it, is a distinct boon; indeed, with a view to avoid polemics, we will magnanimously assume that it is a distinct nuisance. Notwithstanding this, however, it deserves well of the British Public. But for the advent of the electric light we should scarcely have witnessed that sudden determination of the gas engineer to make better use of his opportunities—a determination which has resulted in the "Wenham" and "Welsbach" lights. It is true that the former of these is almost better as a source of heat than as a source of light, and that the latter too often modestly hides its light under a mantle (a broken one, of course), but these devices are nevertheless distinct improvements. But the section of the community which has perhaps derived most benefit is that praiseworthy section which devotes its spare time to municipal affairs. Not only has the arrival of the electric light given a tremendous impetus to municipal management, and thus broken the dull monotony of sanitary and lighting business, but it has afforded an excuse—a very reasonable excuse we hasten to add—not only for jaunts up and down the United Kingdom, but across the stormy waters of the English Channel. And now that electric lighting threatens to become a trifle jejune, electric traction comes upon the scene.

WE have before us the "Report of the Deputation appointed by the Council (of Belfast) to visit various Cities and Towns where Tramway Traction by Electricity is in practice, and Report for the information of the Council." This deputation has certainly not spared itself. Bristol and London, Paris and Brussels, Havre and Hamburg, Berlin and Budapest are a few of the towns "where tramway traction by electricity is in practice" included in the itinerary of this adventurous deputation. And since the result of these wanderings is a splendid "unsolicited testimonial" for electric traction there is nothing, from our point of view, to cavil at. We cannot do better than give prominence to a few quotations from the conclusions come to by the Belfast City Fathers. The italics are ours:—

"After a minute examination of the various systems of mechanical traction obtaining in the cities they have visited, and a careful study of their adaptability to the particular physical and other conditions relating to Belfast, your deputation have come to the conclusion that electrical traction, under certain conditions, is best suited to the wants of the public and requirements of the city. *They believe that any unprejudiced person, after having visited the leading European cities, could come to no other conclusion.* . . . Having regard, therefore, to the fact that

Digitized by Google

all practical objections to the overhead system have been surmounted, and that any exceptions thereto from an æsthetical point of view have been reduced to an almost infinitesimal quantity in the best examples of the overhead system, the deputation feel perfectly confident that they are doing the right thing in recommending that system, with certain stipulations, as the best and most suited to the public interest. . . . The deputation could not fail to observe in the various cities they visited that along what was termed the suburban electrical tramway routes there is, in nearly every case, a rapid development of residential and other property, and a consequent enhancement of the value of the adjacent lands. . . . Their strong impression is that *the travelling public are perfectly satisfied and even delighted with this mode of transit.* This is evidenced in a marked manner by the quickness of the service and the manner in which the cars are filled."

WHAT a commentary upon the absurd attitude of the London County Council! According to this egregious local authority the overhead trolley would endanger the beauties of the Uxbridge-road, and until an economical conduit or accumulator system is forthcoming, no electric tramway traction of any other kind is to be permitted within its jurisdiction! There is, however, one paragraph in the Belfast report, which reminds us of Spring Gardens; it is that in which capitalists are invited to confer upon the Belfast public all the benefits enumerated in the Report, and are expected to be agreeable to being bought out after 14 years "without any allowance for compulsory purchase, goodwill, or other consideration." Belfast may get many things on such terms; it most certainly will not secure electric traction at its best.

THE announcement that coalfields in the vicinity of Dover are to be opened up, by the sinking of a full-sized shaft, should be welcome news for the Dover Electricity Supply Company. During the past nine months, since the commencement of supply, some 57,000 units have been sold for an average price of 3·9d., and have cost on the average 8·80d. per unit. Capital charges have no doubt weighed unusually heavily; for the maximum demand has not exceeded 74 kilowatts, while the station capacity is 325 kilowatts, and we understand that the mains are constructed for a still greater load. But, allowing for the very high capital charges, we are still face to face with works costs amounting to 4·59d. per unit sold, of which no less than 2·28d. went to pay for coal. Or, if we put the question of distribution entirely out of court, whether in regard to the capital expended or the energy losses in the mains, and consider only what has been going on inside the station, we still find that the generating expenses have amounted to 3·34d., of which 1·66d. went to pay for coal, per unit *generated*. This, unhappily, is a "record" in the wrong direction, and compares very unfavourably with, say, Burnley, with its 0·28d. for coal, and 0·78d. for total generating expenses per unit generated. But then the Burnley load factor was 5·77, while that at Dover (for nine months) was only 3·64, per cent., and the facilities for getting cheap coal at the two places are not to be compared.

IN another column we publish an account of some instructive experiments, made in Germany, with a device for putting broken telephone wires, when they break in the vicinity of trolley lines, immediately into good contact with the earth. Although the experiments would seem to show that so far as the protection of a telephone exchange is concerned, fuses can be relied upon to afford good protection, there can scarcely be such a thing as excess of precaution in a matter of this kind, in which valuable property is involved and possibly also human life. Of course, the immediate earthing of a broken telephone wire affords complete protection against shock, and there have been too many instances lately, both on the Continent and in America, of horses and human beings coming into disastrous contact with telephone lines temporarily forming part of a 500-volt traction circuit, for this additional safeguard to be depised.

THE concluding article of a series which has been running for a long time in these columns, and an article by Mr. W. BAXTER from the *Electrical World* of New York, are reminders of the preference that the English electrical engineers have for direct coupling, and of the determination of his American colleague to oust gearing from the unchallenged position it has held in workshops from time immemorial. At modern electric supply stations in this country, rope and belt gearing are now undoubtedly on the wane. On the other hand, we have, up to the present, been slow in using direct-coupled plant for tramway power stations; in fact, there is not a single direct-coupled tramway or railway generator in the United Kingdom. Curiously enough, in America, where they have just rediscovered direct-coupling for engines and dynamos, it is in street railway "power houses" that this re-discovery has been most welcomed, the engines, however, being of the slow-speed type. On the Continent, too, direct-coupled traction generators have found extensive use. The abolition of gearing from workshops is, of course, a different matter, and involves considerations which do not enter into electric generating station practice. Mr. BAXTER's article, while it does not present any new phase of the question, forms a useful summary of the principal considerations which should be taken into account before inducing owners of factories to change over to or to lay down electric motor plant.

Lord Rayleigh.—Lord Rayleigh has been appointed a foreign member of the Copenhagen Academy of Science.

Cable Interruptions.

	Date of Interruption.
Puerto Plata—Martinique	December 19, 1895.
Assab—Massowah	March 29, 1896.

The Amazon Cable.—The cable ship "Faraday" has returned to the Victoria Docks, after having successfully laid the Amazon cable network.

Colour Photography.—A meeting for discussion will be held at the Royal Society next Thursday, when the subject, "Colour Photography," will be introduced by Prof. Lippmann.

Burton-on-Trent.—At the last meeting of the Town Council the report of the Gas and Electric Light Committee recommended that the supply of electrical energy be discontinued, in accordance with the permission of the Board of Trade, during the daytime from April 1st to September 30th. The recommendation was agreed to.

The Endowment of Research.—At a meeting of the Edinburgh University Court, on Tuesday, an intimation was made of a grant to the University of £20,000, out of the bequest left by the late Earl of Moray for the benefit of certain institutions, as a fund for the promotion of original research in the University of Edinburgh, to be called "The Earl of Moray's Endowment."

Digitized by Google

Iron and Steel Institute.—The spring meeting of the Iron and Steel Institute will be held on Thursday and Friday, May 7th and 8th next, at the Institution of Civil Engineers, under the presidency of Sir David Dale. Upon that occasion the Bessemer Gold Medal, which is awarded annually in recognition of meritorious services in advancing the science or practice of the metallurgy of iron and steel, will be presented to Dr. Hermann Wedding, of Berlin. The list of Papers down for reading and discussion is a full and comprehensive one, ten communications being on a variety of metallurgical subjects.

The Physical Society Abstracts.—The Council of the Physical Society, in a circular issued to the members, call attention to the expense attending the publication of abstracts of physical Papers, which has been undertaken by the Society for a little over a year. The proposals now submitted to the consideration of members with a view to meeting this expense are, firstly, that the annual subscription should be raised to two guineas; secondly, that existing life members should pay an annual subscription of one guinea or an additional composition of fifteen guineas; and, lastly, that an annual guarantee fund should be raised for the next five years to cover the probable deficit. Nearly £100 per annum has been already promised.

The Three-Phase Arc.—The three-phase arc, says a writer in *Electricity* of New York, is less noisy than the single phase, and its light is steadier and has less variation in its total intensity, owing to the fact that the current never stops, and there is always a positive carbon. Three cored carbons, placed parallel side by side, with slight magnetising coils to keep the arc at the ends of the carbon, will give a very satisfactory light in the direction away from the tips, and may be used when it is desirable to throw the light all in one direction. Four carbons at 90deg. apart, each with a suitable resistance in series with it, and connected to quarter-phase tap wires on a Gramme ring or other generator giving quarter-phase circuits, will also produce a rotary field arc of great beauty and interest.

Government Appointment.—Mr. John Hesketh, the well-known Borough Electrical Engineer at Blackpool, has been appointed Electrical Adviser to the Government of Queensland, at a salary of £600 per annum and travelling expenses. Mr. Hesketh will have to advise on all matters connected with telegraphy, telephony, electric lighting, and electric traction, and is exceptionally well qualified to do so, since he has served for nine years in the Postal Telegraph service, part of the time under Mr. A. W. Heaviside, and has since been with the Newcastle Electric Supply Company and the Blackpool Corporation. Mr. Hesketh will be known to many of our readers by his excellent translations of M. André Blondel's articles on public lighting which are now running through our columns. Mr. Hesketh was married on Tuesday, and received the cordial congratulations of numerous friends on the happy event.

Errata.—A firm of patent agents have pointed out to us that the patents Nos. 1,769 and 1,830 of 1882, which were said to have expired last week, lapsed, as a matter of fact, some three years ago, through non-payment of renewal fees. Our correspondents remark that "in very few cases do patents in this country last for the full term of 14 years, and even 10 years may be considered a long life." We may add that in these announcements of "Expiring Patents" it is always assumed that the patents have not prematurely lapsed through non-payment of renewal fees. These notes are mainly intended as reminders of the dates of the natural decease of old-time patents, but, alas, as our informants remark, there are many deaths from starvation.

Fothergill Prize.—The Council of the Society of Arts offer the Fothergill prize of £25 and a silver medal for a Paper on "The Best Means of Effectually Preventing the Leakage of Current to Earth in Electrical Installations from Generating Heat and Setting Buildings on Fire." This Paper should consist of about 8,000 words, and be written with a view to being read and discussed at an ordinary meeting of the Society. Papers submitted for the prize must be sent to the secretary on or before October 1, 1896. Each Paper must be typewritten, and bear a motto, the name of the writer being enclosed in a sealed envelope with a similar motto. The judges will be appointed by the Council. The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the judges no essay deserving the full award is sent in.

Niagara as a Manufacturing Centre.—At the conclusion of an article on "Modern Machine Shop Economies," in the current number of the *Engineering Magazine*, Mr. Horace L. Arnold says that "So far the supposed vast advantage of power supplied from Niagara Falls does not cut any figure at all as a dominating factor of shop location. It is even denied that at near by Buffalo Niagara Falls motive power can be furnished more cheaply than steam power, and machine-shop motive power is, in a vast majority of cases, a very small cost item in the grand total of production outlay. A more extended consideration of the subject will, it is believed, fully warrant the conclusion that the character of the workers obtainable, the health and comfort of the workers, and the fixed charges of transportation of both raw material and finished product, should be the considerations deciding the location of a machine shop intending removal from its present location."

The Life of Incandescent Electric Lamps.—The following record of the life of some incandescent lamps used in the engine and machine room of the Great Southern and Western Railway at Cork is given in *Engineering* by Mr. W. M. Smith, District Locomotive Engineer, Great Southern and Western Railway:—

——	Lamps.	Hours.	Maximum life. Hours.
Average life.....	38	3,471	11,005
"	17	2,140	5,468
"	9	5,337	17,880
"	5	1,879	23,434
"	6	6,747	15,517

Lamps Still in Use,

	Hours.
4 lamps which have run over.....	30,000
1 " "	17,600
1 " "	15,000
2 " "	10,000
4 " "	4,000
1 " "	3,400

The lamps are all 50-volt 16 c.p. lamps, and are run off an alternating current circuit.

Physicists of the Impressionist School.—The articles on Röntgen rays now appearing in American newspapers almost daily seem to be too much for Prof. David Starr Jordan, of San Francisco, and he delivers himself in the following way in a local paper:—"Mr. Inglis Rogers and other physicists of the impressionist school are now prominent in the newspapers on account of the supposed relation of their achievements to the discoveries of Prof. Röntgen. Röntgen, and since him many others, have obtained shadow photographs from invisible light vibrations connected with the so-called cathode rays. These light waves passed through matter which is nearly impervious to the ordinary vibrations. Mr. Rogers has produced an impression on the photographic plate by simply gazing on it in the dark. Others claim to do the same by gazing only with the mind's eye, giving a photographic image of the subject of their thoughts. By this means they produce definite chemical action where no material basis for such action exists. Astonishing as all this is, greater works were done in the same line centuries ago. The sages tell us that when Odin and his friend tried to secure the golden mead of the giants, they found it locked up in a stone house. Then they sat down and gazed at the house all day, until by this means they had bored a small hole through the rock walls. This done by concentrated psychic effort, Odin had only to take the form of an angleworm and crawl through the hole to secure the mead. This he did, and, resuming his own form, carried it away with him to Asgard. This seems still more remarkable than any of Mr. Rogers' achievements, because Odin used neither lens nor photographic plate, and recorded his psychic impressions on a bare stone wall. Moreover, the record of his work is better authenticated than that of the recent impressionist photographers. If any one doubts, he will find anywhere the materials to try it for himself. Moreover, the old mythology rests on honest facts of Nature."

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Concluded from page 480.*)

Gearing in Relation to Electric Power Stations.

A short series of articles upon the subject of "Gearing" was contributed by the author to *The Electrician* in August and September, 1892. The construction, working and efficiency of engine and motor gears were discussed in that series. It will suffice, therefore, in the present series to supplement those articles by some discussion of the relation of gearing to the construction and working of an electric power station.

The following forms of gearing are in use at the present time or have been used in the past, in electric power stations:—

I. Single-motion rope gearing, with a free horizontal drive. This class may be subdivided into: (*a*) the American system, consisting of one rope passed several times around both pulleys; and (*b*) the English system, in which each pair of grooves carries a separate rope.

II. Single-motion belt gearing, with a free drive. This class may be sub-divided into: (*a*) horizontal drive, and (*b*) vertical or inclined drive, from one floor to another. Subsystem *b* is largely met with in the United States.

III. Single-motion belt gearing, with jockey pulley. This class is invariably worked with a horizontal drive. It is used in several British power stations, *e.g.*, at Manchester, the City and South London Railway power station, and in some of the Isle of Man railway power stations.

IV. Countershaft double-motion gearing. In this class the engine or engines actuate a countershaft, either by rope or belt gearing, and either on a horizontal, inclined or vertical drive; and the dynamos are driven from pulleys on the countershaft, by ropes or belts. Happily this class is practically obsolete in the United Kingdom; but examples of it are to be met with in the United States and in some of the Colonies.

V. Countershaft single-motion gearing. In this class the engine is direct-coupled to the countershaft, which drives the dynamos by ropes or belts. It is rarely used at the present time, but was formerly adopted in some small stations.

VI. Worm gear. A class exclusively confined to stations using very high speed steam turbines. The gear forms a part of the engine equipment, and the engine and dynamo are on one bed-plate.

VII. Bevel cog gear. Water-power stations in which the turbines drive a vertical shaft, while the dynamos are provided with horizontal shafts, are worked with bevel cog gear. *E.g.*, at the Worcester-Powick station.

The causes which have led to the use of gearing in power stations are numerous. In the majority of places its use may be said to have marked a transition period; some of these places having already emerged from that period, while others are still passing through it. Such a transition period arose from the want of adaptability in speed, between the dynamos and engines. It is the index of instability and lack of finality in engine and dynamo practice, as regards electric power stations. In the early days of electric lighting in this country, for instance, high-speed steam engines were not developed; and the small loads for which dynamos had to be built, together with an imperfect knowledge of dynamo design, led to the entire use of very high-speed dynamos. Some form of gearing, to adapt the slow engine to the fast-moving dynamo, was inevitable. And not until the construction of both dynamos and electric lighting engines had become a matter of importance, was it worth while for engine and dynamo builders to combine to produce plant which could be run without intermediate gearing.

That this cause, though adequate to explain much of the use of gearing, does not cover the whole case, is, however, apparent from the existence of a number of quite modern stations where gearing has been deliberately used. Where these are power stations for railway work, the reason is largely to be found in the lingering belief that direct-coupled railway generators are not reliable, or, at any rate, are not so reliable as rope or belt-driven sets. This, no doubt, will explain the use of gearing in nearly all the railway and tramway power stations in the United Kingdom; though, perhaps, other reasons have existed, in one or two instances, where stock American dynamos have had to be run by engines of British make. When electric traction has grown to be a matter of greater importance in this country, and when engineers here have learned from American practice that direct-coupled railway generators can be made a success, we may expect that the same adaptation of engine and dynamo speed, to enable direct-coupled sets to be used, will occur, as has already occurred in electric lighting stations.

There still remains to explain the causes which have led to the erection of recent electric lighting geared stations. An important factor, no doubt, is the business interests of firms whose steam engines are exclusively adapted to rope or belt driving, such as the makers of mill engines. But this is not the whole reason, for there still exists a class of engineers who disinterestedly believe that the slow-speed steam engine is to be preferred to the high-speed rival, and who, when they cannot get dynamos that can be coupled direct to such engines, have no hesitation in using ropes or belts. Upon these honest advocates of slow-speed geared engines the mantle of the pre-electrical engineers has fallen, and it is little to be doubted that their preference is due to their large experience of the mill engine and their slender acquaintance with the high-speed engine.

Finally we have to notice a cause of gearing practice which, until the last few years, applied especially to alternate-current stations. Until quite recently engineers have found insuperable difficulties in building direct-driven alternators of small or moderate power. Even at the present time the majority of small alternators are rope or belt geared. The cause arises from the necessity to develop a certain frequency of alternation, whatever the size of the machine; and this can only be done by means of peripheral speeds which, in the smaller sizes of alternators, have in the past precluded direct driving. Other considerations have also affected the question, but these are of so electrical a nature as to be beyond the scope of the present series. At the present time, by the use of steam turbines or by modifying the construction of both engine and alternator—as in the flywheel type of alternating current set—moderate, and in some cases even small power can be provided by means of direct-driven plant.

The history of electric power stations in all parts of the world supports the idea of a transition period already mentioned, and clearly shows that the majority of engineers—or, to put it somewhat differently, the weight of engineering opinion—tends to the ultimate elimination of gearing. Two distinct lines of practice have been followed in this resort to direct-driving: (1) the British practice, consisting in the use of high-speed sets; and (2) the Continental practice, consisting in the use of low-speed sets. In the United States there are now distinct signs that the transition period is nearing its close; for the number of direct-driven stations is rapidly on the increase. Both the British and the Continental plans are being adopted, though preference seems to be for the latter.

Influence of Gearing upon Station Construction and Prime Cost.

The use of gearing in an electric power station is very far-reaching in its influence, affecting not only the engine itself, but, indirectly though appreciably, almost every detail of the buildings and works. We will now briefly consider some of its most important effects in this respect; and, to simplify matters, we will confine our numerical considerations to rope-gear, since this is the most commonly-used form of gearing. But it will be understood that the conclusions affect, in a proportionate degree, every form of gearing.

I. **Influence upon the Engine.**—The size of the engine will be increased by the use of gearing: (1) because the additional frictional loss due to the gear will necessitate a greater engine

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

indicated horse-power, and therefore a larger size; and (2) because the use of gearing implies the use of a low speed, and therefore of a larger engine as compared with a high-speed engine of *equal* power. Further, the side stress imposed by the gearing on the pulley will make it necessary to strengthen the engine accordingly.

The actual amount of power lost in gearing has been a matter much debated. The researches of the Committee of the Société Industrielle du Nord de la France, formed to investigate the comparative efficiency of ropes and belts for the transmission of power, threw little or no light upon the matter. A translation of the Report of this Committee was read by Prof. D. S. Capper before the Institution of Mechanical Engineers in October, 1895, and at the discussion on this Report the general opinion seemed to be that the efficiency of a free single-drive rope gear ranges from 90 to 94 per cent. at normal load. It would appear to be practically certain that the frictional resistance of rope or belt gear is constant at all loads, from zero load up to the normal load, so that if the engine is run at constant speed the power lost is constant and independent of the load on the dynamo or engine. We may, therefore, consider the frictional loss arising from the use of rope or belt gearing as being equivalent to an increase in the engine friction equal to from 6 to 10 per cent. of the full engine brake horse-power. Applying this to an engine-dynamo set, we see that to obtain 100 H.P. on the dynamo shaft we must provide an engine giving from 106 B.H.P. to 110 B.H.P., as against only 100 B.H.P. if we have direct driving.

And not only will the size of each engine have to be increased for these reasons, but it not unfrequently happens that in a geared station a much larger unit of dynamo power is adopted, with fewer sets. This would not matter if it did not give rise to an unnecessarily large margin of power in the station. In a direct-driven station the smallest unit is often one-twentieth or a less fraction of the total power of the station; in a rope-driven station it is usually one-fourth or one-fifth, but in some instances it is so great as one-third or even one-half. The effect of this upon the amount of stand-by plant, and on the capital outlay upon machinery is obvious.

II. **Influence upon the Dynamo.**—Assuming the speed of the dynamo to be the same, whether direct-driven or geared, the only effect of using gearing will be to necessitate strengthening the bearings, shaft and certain other parts, and the use of a separate frame, bed plate and foundations, with appliances for adjusting the length of the drive when the gearing wears slack.

III. **Influence upon the Boiler Plant.**—The boiler plant and, in fact, the entire equipment of the boiler house, as well as the steam mains, will have to be constructed to deliver at full load an additional amount of steam per hour, corresponding to the extra consumption which the larger size of engine and the gearing losses will involve. This additional capacity will be in simple proportion to the additional indicated horse-power of the engine plant.

IV. **Influence upon the Buildings and Area of Site.**—In the majority of British electric power stations the engines and dynamos are on the same floor, the former being in some few cases raised above the dynamo level to facilitate rope driving with large pulleys. In these stations, therefore, the use of gearing involves additional floor space and a larger machinery room. A type of station commonly met with in America, but very rarely seen on this side of the Atlantic, has an engine floor below the dynamo floor, the dynamos being driven by belts passing through the dynamo floor. In this case the area of site is not increased, but the height and cost of the building will be augmented, as compared with a direct-driven station. Moreover, in all geared stations, the fact that the engines themselves occupy more space, apart from the space covered by the rope drive, should not be overlooked; but this is a matter which only enters into the comparison of geared stations with *high-speed* direct-driven stations. The allotment of floor area in a number of electric power stations is given in detail in Table XXXVII.

V. **Influence upon the Prime Cost of the Station.**—A comparative study of the capital outlay effected by the various electric supply concerns in the United Kingdom leaves no room for doubt that the use of gearing, as opposed to direct-driving at high or moderate speed, does affect prejudicially the capital cost of the station. Nor could this be otherwise, considering the influence which the use of gearing has upon the various items already enumerated. Yet it is at first sight a matter for some surprise, that the comparison between the actual costs of geared and direct-driven stations does not show that great and invariable difference which the foregoing considerations might lead one to expect. The author has compiled Table XXXVIII. from the reports for 1895, issued, under the direction of the Board of Trade, by the various electric supply concerns enumerated. This Table gives the capital outlay, per 8 c.p. lamp of station capacity, for the entire station, including the cost of lands, buildings and machinery, but excluding the cost of transformers, accumulators, mains, switchboards and instruments. In a parallel column is given the cost, per 8 c.p. lamp of station capacity, of the generating machinery alone, including boilers, engines and dynamos, with all their auxiliary generating plant, but excluding transformers, accumulators, mains, switchboards and instruments. It is to be regretted that the published capital accounts do not permit of further analysis, for it is highly probable that a comparison of the cost of engines alone, per 8 c.p. lamp, would have shown even greater differences between the geared and the direct-driven stations.

By way of comment upon Table XXXVIII., it may be pointed out that the figures tend to show much more that the geared stations have been placed in small country stations or at distances from towns where land can be had cheaply, than that they have actually cost more than the direct-driven stations. Thus, a direct-driven London station may have cost actually more per 8 c.p. lamp of station capacity, than a rope-geared station, owing to the enormously higher cost of land per square foot, the extra sum paid for better buildings, and the cost of bringing the machinery to town and erecting it there. In support of this interpretation the author would call attention to Table XXXIX., which gives the proportion of geared and of direct-driven stations in large cities and in country towns in the United Kingdom.

In compiling this table stations which are equipped with both geared and direct-driven sets have been omitted.

Table XXXVII.—*Showing the Influence of Gearing upon the Floor Area of the Machinery Room in Electric Power Stations.*

Place.	Capacity of station in kilowatts.	Type of engines.	Arrangement of gearing or coupling.	* Sq. ft. gr'ss area per kilowatt.	* Sq. ft. net area per kilowatt.
Bristol	1,316	Vertical, high-speed.	Direct-coupled.	1·938	1·276
Brighton	810	Vertical, high-speed.	Direct-coupled.	3·024	1·518
Portsmouth ...	848	Horizontal, low-speed.	Direct-coupled.	4·068	2·948
Amsterdam ...	1,335	Horizontal, low-speed.	Direct-coupled.	4·768	3·018
Manchester ...	1,320	Vertical, low-speed.	Belts, with jockey pulleys.	4·848	3·333
Dublin-Dalkey (elec. tramw'y)	440	Vertical, high-speed.	Belts, free drive.	5·102	3·432
Cologne	1,160	Horizontal, low-speed.	Direct-coupled.	6·455	4·095
Belfast (gas engines).	393	Horizontal, tandem, low-speed.	Rope drive.	5·458	4·580
Amberley-road, London.	600	Horizontal, low-speed.	Rope drive.	9·666	4·753
Worcester (steam and water).	500	Vertical, moderate-speed, with water turbines.	Rope drive.	6·860	5·750
Wolverhampt'n	485	Horizontal, low-speed.	Rope drive.	8·907	5·752
Coatbridge (gas engines).	150	Horizontal, low-speed.	Rope drive.	16·467	10·133

* By gross area is meant the total area of the floor already occupied by the plant; and by net area is meant the gross area, *less* the uncovered space surrounding the block of machinery. The net area includes the floor covered by the engines, gear and dynamos, and the gangways between the separate sets of plant, but not the gangways surrounding the entire plant.

Influence of Gearing upon Annual Expenses.

In the same way that gearing exerts an intricate influence on the amount of the capital outlay for a station, so will it affect many of the items of the annual expenses involved in running the station. We will now consider its influence in this respect, commencing with the generating expenses.

I. **Influence upon the Coal Bill.**—It has already been stated that at full load rope gear involves a loss of from 6 per cent. to 10 per cent. of the brake horse-power which is supplied to it, and that it wastes this *amount* of power during all the time that it is run at full speed. Considering this last as being equivalent to an increase of engine friction by an equal amount, we may calculate the reduction in efficiency of the engine-dynamo set, and the steam consumption, in the same manner as we have already, in a previous article, obtained the relation of the brake horse-power consumption to the indicated horse-power consumption of the engine itself. In this way we may obtain, for any engine and set of gearing, a Table similar to Table XL., which latter has been compiled on the following assumptions:—It has been assumed that 100 B.H.P. full load is required at the dynamo shaft, and that in one case this is supplied by an engine of 100 B.H.P., direct-driving, while in another case it is supplied by a proportionately larger engine, rope-geared. The steam consumption is assumed to follow Willans' straight-line law, and the two engines being of such nearly equal power, it is assumed that the *constant* loss of steam is proportional to the rated horse-power, and this constant has been taken at 500lb. for the direct-coupled engine and (*pro rata*) at 550lb. for the geared engine. These data are sufficiently removed from laboratory or test conditions to give practical value to the results. Thus the steam consumptions are taken according to the equations:—

$W = 500 + 15\ P$ . . . (for the direct-coupled engine), and

$W = 550 + 15\ P$ . . . (for the rope-geared engine) where W is the weight of steam per hour, and P is the brake horse-power developed at the *engine* shaft. The efficiency of the rope gearing at full load has been taken at 90 per cent.

It will be seen that, under the conditions assumed in Table XL., the effect of gearing is to increase the steam consumption by *at least* 10 per cent. This minimum augmentation occurs at full load; but the increase becomes greater as the load falls, so much so that at half dynamo load the gearing involves an increase of 16 per cent. in steam consumption; while at quarter load the increase is nearly 23 per cent. Obviously, the way to minimise this effect is to keep the set on a high load factor, and to avoid very low loads. But it is to be noticed that it is more difficult to do this, in proportion as the power of the station is contained in few sets; and that geared sets are, as a rule, larger units—in proportion to the station power—than direct-driven sets. Consequently, there must be a greater tendency in geared sets to run to low engine load factors, and a consequently greater loss by augmented consumption of steam and coal. In quite lurid confirmation of this the consumption of coal at the Worcester steam and water-power station may be cited. According to the official report of the resident engineer, the lack of water-power made it necessary to run the steam engines on low day loads for long periods. As a consequence, the engines being rope geared, the coal cost no less than 0·745d. per unit generated, including the units generated by the water-power.

Table XL.—*Showing the Influence of Gearing upon the Engine Brake Horse-power required to Supply 100 B.H.P. to a Dynamo, and on the Consumption of Steam per Hour and per useful Horse-power per Hour, when the Dynamo is running at various Fractions of Full Load.*

B.H.P. to be supplied to dynamo.	B.H.P. to be developed by steam engine.		Steam consumption in lb. per hour.		Steam consumption in lb. per hour per useful B.H.P. at dynamo.	
	Direct-driving.	Rope-geared.	Direct-driving.	Rope-geared.	Direct-driving.	Rope-geared.
100	100	110	2,000	2,200	20·00	22·00
90	90	100	1,820	2,020	20·22	22·44

0	0	10	500	700	...	...

II. **Influence upon the Generating Expenses.**—Not only the cost of coal, but other items in the generating expenses are affected by the use of gearing. It may be a disputed point whether more oil and waste will be used in every case if gearing be resorted to, though the author is inclined to believe that more would generally have to be used. Certainly more water will be used; and where water has to be purchased, or to be handled at any expense, the cost will be proportionately raised by the use of gearing. Repairs and maintenance of the machinery may also be affected by the use of gearing, though the point is open to doubt. It has been claimed that low-speed engines do not wear so fast as high-speed engines, a matter which may possibly be conceded in the case of vertical engines. In order to settle this point by appeal to actual stations, it would be necessary to examine the sums paid for repairs and maintenance over a considerable number of years; and the manner in which the accounts are rendered does not facilitate this, at present. In Table XLI. the author has analysed the influence of gearing upon the total generating expenses of a number of stations in the United Kingdom; and a parallel column gives the cost of coal at these stations. The extremely large variations in the prices paid for coal considerably affect the relative costs of various stations. The

* The lamp capacities are taken from "*The Electrician*" *Electrical Trades' Directory and Handbook for 1896.*

Digitized by Google

statistics are for the year ending December 31, 1895; and the costs are given per Board of Trade unit generated, as measured at the station switchboard.

Table XLI.—*Showing the Relation of the Type of Engine and Method of Coupling or Gearing, in some Electric Supply Stations, to the Generating Expenses per Board of Trade Unit Generated.**

Type of engine and method of coupling.	Place of station.	Units generated in 1895.	Generating expenses per unit generated, in pence.	Cost of coal per unit generated, in pence.

	Worcester†	348,251	1·6034	0·7454

III. **Influence upon the Management Expenses, &c.**—The items of expense included under "rent, rates and taxes" will to some extent be affected by the use of gearing, inasmuch as the station will cover a larger area of land, and will also involve a larger capital outlay on buildings and machinery, to be taxed. The item of "rent" cannot well be analysed in the official accounts, as the stations covering greater areas per unit of power are usually situated where land is cheaper. As to rates and taxes, the erratic manner in which these are assessed makes any analysis impossible. A direct comparative study of the sums paid for "management" does not yield any fruitful result, as the effect of using gearing is probably very involved. The history of electric supply, both in this country and in America, however, will furnish non-mathematical data from which it could be inferred that the management is often largely influenced by the behaviour of gearing. Where a station is suddenly extinguished during a busy hour on a Saturday night, and the cause is directly due to the parting of a rope gear, or where the same thing occurs on account of a belt leaving the pulley, a considerable loss of revenue occurs that will not be directly laid to the account of the gearing, but which would have been prevented by the use of direct-driven sets.

In conclusion, it may fairly safely be predicted that the use of gearing in both electric supply and electric traction stations will gradually disappear. So far as those stations which are already equipped with geared plant are concerned, it seems most probable that when extensions and renewals of plant take place direct-driven sets will gradually replace the present plant. And as regards stations for the development of tractive power, the success which the direct-coupled railway generator is meeting with in America cannot fail to lead ultimately to the abandonment of the use of gearing in these also.

Motocycle Civilisation.—"When the motocycle has performed its work," says a writer on "Horseless Carriages," in *Cassier's Magazine*, "it may be run into the shed or into the parlour after cleaning it. If the owner chooses, he may fit it with a coueh and make it a common article of furniture in the house."

* So few electric supply concerns publish, in their annual returns, the number of units generated, that this Table necessarily covers only a very limited number of stations. It is hoped to expand it as data increase.

† The Worcester station is partially driven by water power, but the units generated by this means are not distinguished, in the accounts, from those generated by steam. The generating expenses and cost of coal are therefore for each unit of the *total* number of units generated.

THE CALCIUM CARBIDE PLANTS AT SPRAY AND NIAGARA FALLS.

The carbide plant at Niagara Falls is the first to be erected and operated in America outside the parent plant in Spray, N.C., illustrations (Figs. 1 and 2) of the furnace of which and the electrode are given in connection with this article. Coke and lime are the simple and cheap ingredients from which calcium carbide is made. When finely divided and intimately mixed they are smelted together in an electric arc furnace.

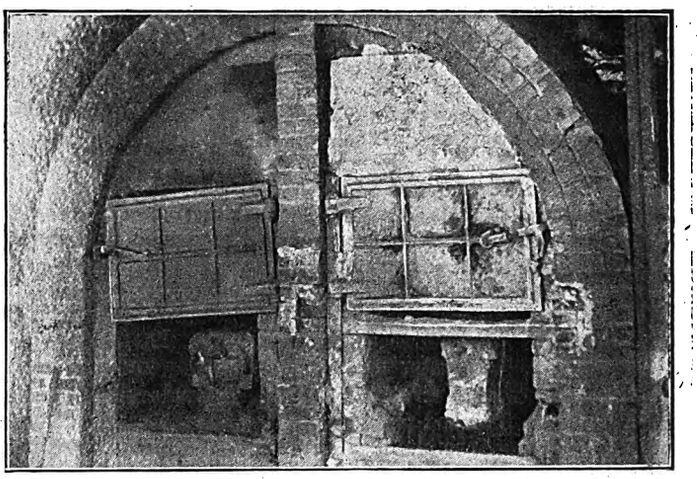

Fig. 1.—Calcium Carbide Electric Furnace at Spray, N.C.

Any form of carbon can be used, but coke gives the best results; any form of lime, either burnt lime, limestone, or slacked lime, but quicklime gives the best results. The coke is ground to an impalpable powder with crushers and rollers, then sieved through a 50-mesh sieve. The lime is crushed and ground the same way, but not sifted. The coke and lime are then weighed out in proper proportions and mixed in a mechanical mixer. It is impossible to overestimate the importance of finely crushing the constituents and of thoroughly mixing them. From the mixing machine the

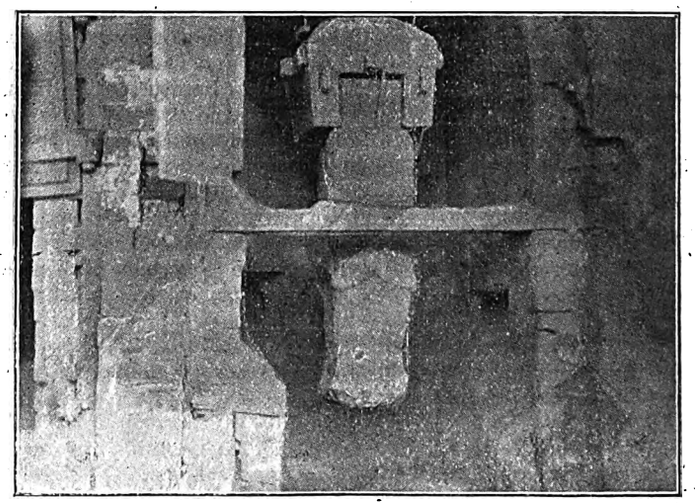

Fig. 2.—Electrode of Calcium Carbide Furnace.

mixed material is carried to the electric furnace. A supply for as long a time as the design of the building will permit can be stored. No deterioration takes place after the mixing of the materials. The lime air-slacks to a very limited extent. This, however, makes very little difference.

Each of the four furnaces at Niagara contains a cast-iron crucible 8ft. 6in. long, 2ft. 8in. deep, and 2ft. 2in. wide. The electric furnace consists of a horizontal bed plate or crucible connected to one pole of the generator or transformer, and of a vertical carbon pencil connected to the other pole, suspended

Digitized by Google

above the centre and capable of moving in a vertical direction. The process is started by attaching the carbon pencil to the bed-plate. The carbon pencil is then raised, imposing an air gap in the circuit. Having established the arc in this manner, the material is fed in towards the crucible or bed-plate covering the arc and surrounding the pencil to a depth of from 2ft. to 3ft. The production of carbide begins immediately. The carbide thus produced forms under the pencil, and tends to close the air gap. As the air gap is shortened the resistance of the furnace is lowered, and the attendant in charge then raises the pencil so as to lengthen the air gap. This adjustment is necessary every few minutes. One man of ordinary intelligence can attend four furnaces. An ammeter showing the flow of current to each furnace is placed in immediate proximity to the carbon-raising device. After the process has been going on in this manner for from one to three hours, a column of carbide from 1ft. to 4ft. in diameter is formed between the bed-plate and the bottom of the carbon pencil, the arc being maintained between the top of the column of carbide and the bottom of the pencil. As the carbide formed is a substance of more or less high electrical resistance, and as this remains in circuit after it is formed, it is economical to stop the process, clear out the crucible, and make a new start after a column of 2ft. to 6ft.—according to the capacity of the furnace—has been produced. The process of drawing a charge consumes from three to five minutes. The carbide is then allowed to cool, after which it is broken up and may be stored.

Each of the furnaces at Niagara is designed to consume 500 H.P. The bed-plate in the furnaces at Niagara consists of a cast-iron crucible placed on a car, which is run into the furnace on a track under the carbon pencil. A clamping device makes the necessary electrical contact on the side of the crucible. The pencils consist of six carbon slabs 46in. long, 4in. thick, 8in. wide at lower end, and 16in. wide at the upper. These are clamped in a cast-iron holder, which in turn is secured to the end of a copper rod 3½in. by 3½in. Flexible copper cables are fastened into the upper end of this rod, to permit of a vertical movement of about 12ft. The carbon pencils, the carbon holder and the rod are all counterpoised to lessen the work of raising and lowering the electrode. After the arc is started the mixed material is fed into the crucible by opening a shoot and allowing it to drop in from a bin located above the furnaces.

The furnaces are of simple construction. They consist merely of retaining walls of ordinary red brick to prevent the material from flying about and being blown mechanically out of the crucible. Carbide has been and can be made on an open hearth without any side walls whatever. The furnaces for the present are wired in parallel, and two will be in operation at the same time. Some dioxide of carbon is produced during the process, and this carries out of the furnace mechanically a small portion of the lime and coke. To provide a settling chamber in which this can be recovered, a flue 12ft. long, with hanging walls and diaphragm, is built at the back of the furnaces and along the floor to a vent at some convenient point. Each 500 H.P. furnace will, it is asserted, produce in one day about 2½ tons of carbide.

The electrical equipment of the plant at Niagara consists of one 1,000 H.P. single-phase transformer and a "reactive" coil, to be used in starting the furnaces. The is also a 75 H.P. two-phase 2,000-volt motor running at 375 revolutions. This 75 H.P. motor is used for operating the crushing, grinding and mixing machines, elevators and conveyances. The electrical equipment was furnished by the General Electric Company, of Schenectady, N.Y., and Lynn, Mass.

At the time of writing but little remains to be done at the Niagara factory before it is operated. Some delay has been caused by the failure or oversight to make proper water connections, and this is now being done. The power for the plant will be obtained from the Niagara Falls Power Company, and as the factory site is some distance beyond the end of the subway, the cables are carried in boxes placed just above ground, and will so remain until the subway is extended, which probably will be this spring. It is highly probable that before this article is in print the electric current will be turned into the furnaces.

DESCRIPTION OF GEAR FOR THE JAPANESE SUBMARINE CABLE STEAMER, "OKINWA MARU."

Some months ago we announced that the new Japanese Government steamer, the "Okinwa Maru," would be equipped with cable-gear by Messrs. Johnson and Phillips, who had also secured the order for fitting the vessel throughout with electric lighting plant and fittings. We now give particulars of this equipment. The combined picking-up and paying-out gear, as shown in the photographs which we reproduce, is very compact, and has been constructed principally of steel so as to combine strength with lightness, the weight all told being only about 21 tons.

Although specified to pick up under a strain of 25 tons at 175lb. pressure, we understand that the gear on official trial showed itself equal to a much greater pressure. Compared with the gear by the same makers fitted on the "John Pender," "Great Northern," "Chiltern," "Electra," "Magneta," "Recorder," "Relay," "Citta de Milano," and many other steamers, it is equally powerful as the three first named, and twice as powerful as the others, while at the same time it is lighter and more compact.

The gear stands on a strong steel girder bed on the main deck, and the drums (which may be worked separately or together at will), &c., project through a hatch in the spar deck, and this is fitted with covers which form the driving platform for the machine. The gear has overhung drums, 6ft. 3in. in diameter by 2ft. 6in. wide, internally geared, and running loose on a fixed shaft carried on two steel frames, and is arranged for four speeds. The motive power consists of one vertical compound engine, having cylinders 12in. and 24in. in diameter by 14in. stroke, capable of developing 265 H.P. without the use of the condenser, in conjunction with which it will, however, generally be used. The engine is fitted with link-motion reversing gear, and also with automatic bye-pass valve for admitting high-pressure steam to low-pressure cylinder for starting. The crankshaft is geared to the first motion shaft of the machine by means of double-helical bevil gear. When it is desired to pay out without steam power, the only moving portion of the machine is the drum, which is readily controlled by the brake. To enable the drum to revolve independently of any other part of the gearing, provision had to be made for sliding the drum pinions out of gear, and as it was essential to keep the drums close up to the frames, these pinions have been arranged to draw through the frames. This has been effected in a very neat manner by the makers, two large holes being cut in the frame plates and a large pocket casting fitting into these, carrying bearings each side of the frames, so that the pinions which gear into drums run between two bearings, the arms of the drum being set back to allow for this outer bearing, and this arrangement ensures a very substantial job. These pinions are put into and out of gear by means of a combination of hand-wheels, screws and bellcrank levers. All wheels are arranged to draw out of gear when necessary, so that only the particular set required needs to be in gear. Fig. 1 shows a general view of the gear and engines.

The brake straps are of steel plate, fitted with elm blocks. The lower parts of the straps have large cast-iron eyes attached to them, and these are kept in position by means of a shaft of 3½in. diameter, which passes through both frames.

The brake power is applied by means of right and left hand screws working in nuts attached to the upper parts of the straps, the screws being actuated by means of hand-wheels from the starting platform, and when the straps grip the brake drum the pull is transmitted to the machine frames (through the before-mentioned eyes and shaft) and thus to the deck of the vessel. A water service is provided for the brakes, the water being distributed by means of a small Worthington pump.

Each drum is provided with two "knives" for fleeting the cable on the drums to suit either an inside or outside lead, as the case may be. A convenient arrangement is that the working face of each knife is fitted with a hard steel liner capable of being easily unscrewed and renewed when worn.

Digitized by Google

There are three sheaves at the bows, 51in. diameter by 11in. wide, the two outer ones being V-section and the middle one U-section. These sheaves are of steel, with gun-metal bushes, and they are arranged to run loose on a steel shaft fixed in blocks carried on four steel girders, which are built into the ship for a distance of several feet, being connected to the beams and to the steel deck, thus ensuring a very substantial job. Each sheave is provided with a cast-iron "whisker," or guard at each side, to prevent the cable from coming off. The two outer whiskers carry davits with a cross-bar for convenience in launching mushrooms, grapnels, &c. The side plating of the ship is carried out to meet these castings, thus giving the bows a very neat appearance.

This has but one sheave, which is 38½in. diameter by 11½in. wide, and is fitted with gun-metal liner to run loose on a shaft fixed on blocks carried by rolled girders. These girders are attached to the deck by means of special castings, which also serve to secure the necessary stopper hooks.

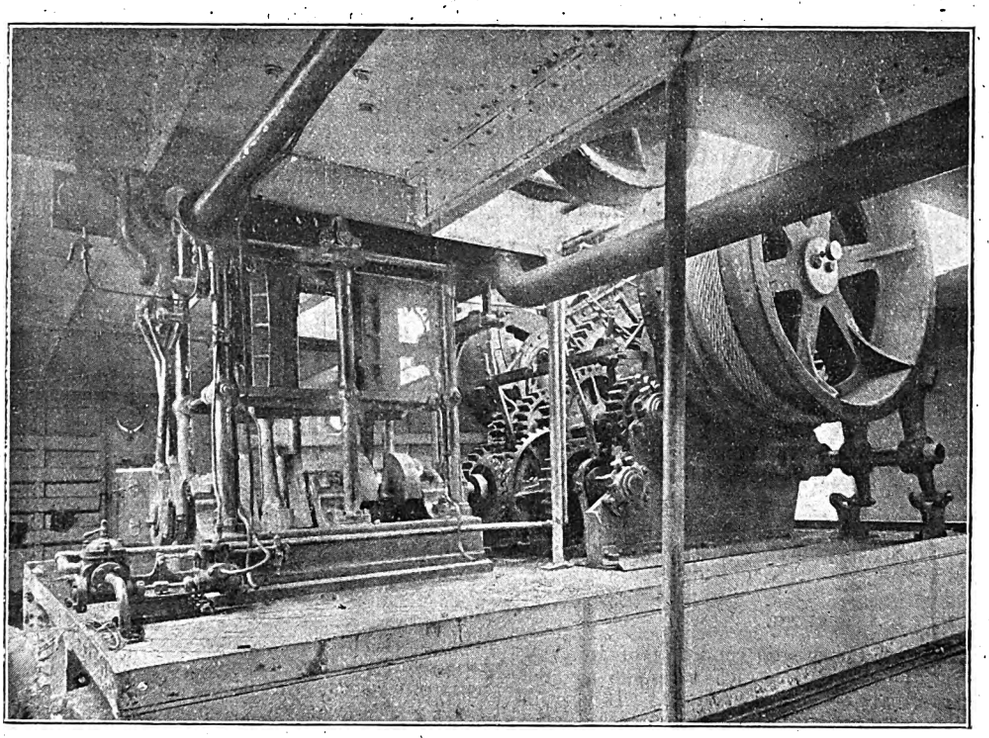

Fig. 1.—General View of Gear and Engines of the Cable Steamer "Okinwa Maru."

The cable machine is placed just aft of the foremast and between it and the bow sheaves are the two dynamometers, one for each drum, the necessary leads being placed at a certain distance on each side of the dynamometers. Fig. 2 is a view of the spar deck looking forward, and shows the dynamometers and gear, as well as the above-mentioned hand wheels needed for the application of brake-power.

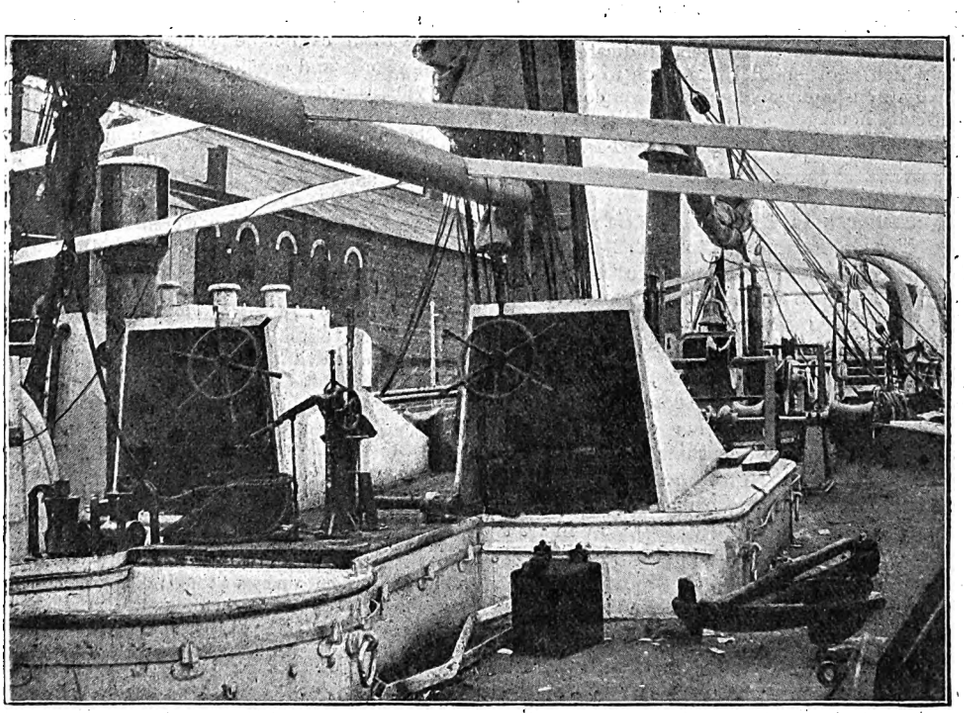

Fig. 2.—View of Spar Deck, looking Forward.

The dynamometers are of Messrs. Johnson and Phillips'

Digitized by Google

design, consisting of cast-iron footstep with steel cylinders, on which a large cast-iron sleeve slides, and to this sleeve the sheave is attached, and also two side rods which carry a crosshead some distance above. To the crosshead is attached a piston rod with piston, which works on the outside of the steel cylinder, which is filled with oil, and the piston being a loose fit, this acts as a dash-pot to steady the movement. The top of the steel cylinder is, of course, fitted with a packed gland.

The "Okinwa Maru" was launched on Friday last from Messrs. Lobnitz's yard at Renfrew. She is 290ft. long, 40ft. beam, and depth 24ft. 6in. moulded. The electric lighting arrangements are very complete, the generating plant being provided in duplicate. Duplex electric mast and side lights are provided, and a complete outfit of portable electric lamps for outside use when the vessel is engaged on cable work. The whole of the electric lighting work has been carried out by Messrs. W. C. Martin and Co., of Glasgow.

The Japanese Government, with its characteristic enterprise, appears to have secured a cable ship which will compare favourably with any similar craft afloat. The cable equipment of the "Okinwa Maru" contains many useful novelties, and is in every respect, even to its galvanometers, which are of the Sullivan type, up-to-date.

THE EXAMINATION OF MAGNETIC HOMOGENEITY IN IRON AND STEEL BY MEANS OF ELECTRIC CONDUCTIVITY.*

BY DR. A. EBELING.

Since the examination of the magnetic condition of iron by magnetic methods is a very lengthy process, it is desirable to find some more rapid method of testing for inequalities. It is well known that the electrical conductivity of soft wrought iron is higher than that of soft steel, and the following experiments were carried out to ascertain if there is a direct relationship between the magnetic and electrical properties. Samples of iron and steel were tested magnetically, and were also examined for conductivity throughout their length. This latter test was performed by sending an electric current through the metal, and observing the fall of potential over a constant length at different points along the bar. Since the bars were all carefully turned to a uniform cross-section, the fall of potential was proportional to the mean specific resistance over the length between the contacts.

The result of the examination of some 20 pieces indicates that those iron and steel rods which show small differences in conductivity are also magnetically non-homogenous. To the converse statement that all magnetically homogeneous materials also possess uniform conductivity, there are, however, exceptions (*sic*).

High Admission Requirements in Engineering Schools.—In a leading article in its issue of February 13th, the *American Machinist* criticises the modern tendency to increase the standard of requirements for admission to engineering schools. This is regarded as the most unfortunate development of the educational system in these schools. "High admission requirements are supposed to test the ability of the applicants, and to sift out those who are least capable of pursuing the course of study with profit. In point of fact, they do nothing of the kind. Instead of testing the abilities of the student, their real effect is to test his opportunities, and to sift out those who, by reason of location, occupation, or lack of means, have been denied access to the best preparatory schools. We do not for a moment imagine this to be their object, but it is undoubtedly their effect. . . . Now, if it is desired to keep down the number of applicants, how would it do to require them to have served an apprenticeship in a machine shop? We do not doubt this would be still more effective than the present plan with a large number of the present class of applicants. Or, if this is considered too revolutionary, what is to prevent an arrangement by which previous shop experience should offset some of the more advanced of the present requirements. The time which the present class of students devote to shop work being given by the new class to the preparatory studies in which they would be deficient?"

* Abstract from the *Zeitschrift fur Instrumentenkunde.*

ADVANCES IN THE THEORY AND CONSTRUCTION OF SECONDARY BATTERIES.*

BY F. ZACHARIAS.

All lead batteries, as is well known, suffer from want of cohesion of the active material, even the Planté and Tudor types being no exceptions, for as soon as the oxidation has penetrated to a certain depth, the oxide begins to flake off. The latter types are not suitable for traction purposes on account of their great weight and small capacity. Careful observation and experiment have led to the conclusion that it is the formation of bubbles of gas at the contact of the active material and the support which leads to the destruction of the plates. As the evolution of gas cannot be prevented, means must be provided to facilitate its escape. All mechanical contrivances for strengthening the plates, such as grids and trellises, have failed, for the more rigidly the paste is contained the sooner the destruction of the plate follows, since the gas can only escape through the surface of the paste, which becomes disintegrated in consequence.

What part "Gassing" plays in the destruction of the plate can be best ascertained by the study of a plate in which no provision is made for the escape of gas. After about the fifth charge a small portion of the paste falls from the centre of each plug, but this is obviated if about 100 perforations per square decimetre have been made in the paste with a needle before the plate is formed. The process of forming in plug plates takes place inwards in concentric zones, since the current can only enter the paste from the edge of the plate. Thus the edge portions are formed before the centre, and an injurious strain is set up, which causes the destruction of the active material sooner or later, according to its density or porosity. Provision for the escape of gas from the negative plates is also absolutely necessary, or else the powdery reduced lead on their surfaces is blown off by the gas bubbles. Plug plates have the largest capacity for a given weight, and in them about one-third of the total weight is due to the frame, so in any improved plate this proportion must be approximately adhered to. A paste formed with sulphuric acid does not yield satisfactory results, therefore some other mode of formation must be employed. What is required is a plate of firm, porous, active conducting material of high capacity and small initial cost, so that within limits the durability need not be of primary importance.

The existing plug plate is not suitable for two reasons—first, because, owing to the narrow lead frame surrounding it, it can only be employed with low rates of charge and discharge; and, secondly, because in both the positive and negative plates the action of the current weakens the contact of the paste with the frame, so that the former is liable to drop out. Plates larger than 16cm. by 13cm. cannot be profitably employed.

These results and considerations led to the construction of plates embodying the following five principles:—(1) No portion of the metallic frame should pass horizontally through the paste; (2) the paste should not be retained at its upper edge by the metal frame, but should be free to expand and gas; (3) wherever the frame covers the active material it should be perforated to allow of the escape of gas: (4) the frame should distribute the current evenly, and have the least possible weight consistent with strength and securing the paste; (5) the frame should be so constructed that the material of the negative plates should not lose contact, even when disintegrated.

In the plates so constructed by Zacharias and Dannert all the parts of the plate retaining the paste are perpendicular, and in those plates whose thickness is greater than 15mm. perpendicular strips are also embedded in the paste, so that the surface of the paste in contact with the support is equal to or greater than that in contact with the acid. Great care is taken to provide for the escape of the gas, both in the frame and in the active material, and in the case of thick plates channels even are cut in the paste. It is claimed for these plates that they begin to give off gas during charge earlier than those hitherto employed, but that the gas escapes without forming the large bubbles which disintegrate the paste. After a year's experimental work it was found that an organic substance was most suitable for the preparation of the paste, and it is claimed that with the new plate a capacity of 100 ampere-hours per kilogramme of active material, or 65 ampere-hours per kilogramme of positive electrode can be obtained. The rate of charge is given as 1-2 ampere per square decimetre of surface of the positive plate, while a discharge rate of up to 5 amperes per square decimetre is admissible. Experiments have further shown that in order to obtain the best results the preparation of the paste, as well as the arrangement of the supports, must be altered to suit the requirements of each particular class of work.

Further particulars are promised as soon as the patent rights have been secured in all countries.

A CONTRIBUTION TO THE THEORY OF LEAD BATTERIES.*

BY DR. WALTHER LÖBB.

Under the above title C. Liebenow recently published his views concerning the reactions which occur in lead batteries, for which he sought a simple explanation, without involving the adoption of Le Blanc's hypothesis of the fourfold valency of lead ions. Working on different lines, the author has been led to adopt Liebenow's opinions in the main, and he hopes shortly to be able to give full experimental proof of them, but in the meantime he publishes a short note on the subject.

In the case of the electrolysis of organic lead salts, the simultaneous deposition of lead and lead peroxide can be obtained without any evolution of gas, and the quantitative estimation of the organic acid made after the cessation of the operation shows that the acid is unaltered.

The author argues that the lead has been replaced by hydrogen from the water, and that the appearance of lead peroxide at the anode cannot be due to the electrolytically evolved oxygen. The lead peroxide probably exists as such in solution, and the oxygen necessary for its formation is obtained from the water.

So far these conclusions are in accord with Liebenow's, but with regard to the part played by water, the author differs, for, in his view, water which acts as a solvent cannot be regarded as a pure liquid; but just as one speaks of the solution and concentration of an electrolyte in water, so the corresponding solution of the water in the electrolyte must be accepted. The liquid resulting from the solution of sulphuric acid in water, can be as well regarded as a solution of water in sulphuric acid, and all reactions which require the separation of the water into oxygen and hydroxyl, and thus represent hydrolytic dissociations, are only explicable as ion reactions if one admits that the capacity to produce oxygen and hydroxyl ions depends on the nature of the body dissolved in the water.

This theory and its results are discussed, and the conclusion arrived at is that the electrolyte is hydrolytically dissociated. The peculiar properties of the lead hydroxide enable it to form oxygen ions as well as hydroxyl ions, *i.e.*, to act as an acid as well as a base, and to this property is due the possibility of the hydrolytic dissociation of neutral lead salts. The appearance of metallic lead denotes the dissociation into lead and acid residue, while that of lead peroxide shows the presence of this ion, which can only be produced by the hydrolytic dissociation of part of the salt.

If only a low current density be employed, the electrolysis of a solution of benzoate of lead can be made to yield only lead and lead peroxide, no gas being evolved, which means that half the salt is electrolytically decomposed and the other half hydrolytically. Under these conditions it appears that as lead and lead peroxide are electrically equivalent, the whole amount of acid remains unchanged in the liquid, as there are four hydrogen ions to regenerate the four acid residues. The dissociation conditions are not always so simple, but from many lead salts the metal and the peroxide deposited are exactly equivalent. It is only under these conditions that no gas is evolved, but the organic acid is always unchanged.

The dual nature of lead hydroxide, which has also been dwelt on by Liebenow, can be easily proved by the electrolysis of an alkaline salt of lead hydroxide, which yields lead and lead peroxide simultaneously.

In considering the case of lead batteries, more prominence must be given to the part played by water, and its dissociation into hydrogen and hydroxyl ions, for it renders possible the formation of lead peroxide: and, owing to the slight solubility of lead sulphate, the conductivity of the electrolyte depends solely on the dilution of the sulphuric acid, *i.e.*, on the ions which yield sulphuric acid under the dissociating influence of the water, and *vice versâ*.

SAFETY DEVICES FOR TELEPHONE CIRCUITS.†

BY F. MERTSCHING.

At Remscheid, a short time ago, a broken telephone wire came into contact with the overhead conductor of the electric tramway, causing a serious fire in the telephone exchange. This occurrence brought at once to the front the question of how best to prevent heavy currents from entering telephone circuits. At present there are several devices in use. In cases where only a few telephone wires cross the trolley line of a tramway, india-rubber insulated bronze wires can be employed as telephone conductors. It is, however, by far the most common practice to protect the overhead conductor of the tramway by means of a cover. Devices used by the Allgemeine Elektricitäts Gesellschaft are shown in Figs. 1 and 2. In Fig. 1 insulation is afforded by a split india-rubber tube screwed to the top of the conductor. The screws are soldered to the conductor, and large nuts of "stabilit" are employed to ensure good insulation, and prevent a telephone wire from being taken along by a passing trolley. Another device consists of a strip of impregnated wood of the section, shown in Fig. 2, carried by T-shaped brackets soldered to the conductor. As the wooden strip has a slot along the entire length, the different expansions of wood and copper are compensated for. Another way of protecting telephone circuits, especially where a great number cross a tramway, is to fix a wire netting, well earthed, underneath the telephone circuit. Still another arrangement is suggested in a German patent, in which a falling wire disconnects itself at the pole.

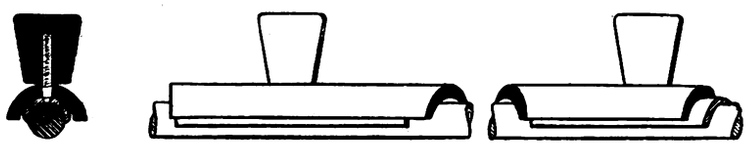

Fig 1.

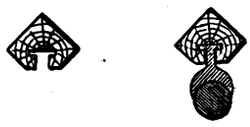

Fig. 2.

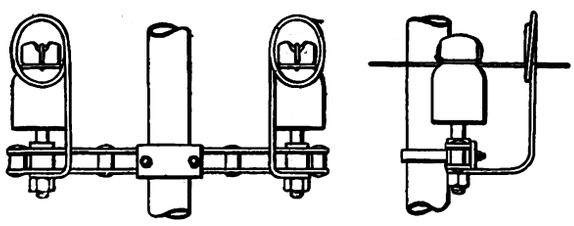

Fig. 3.

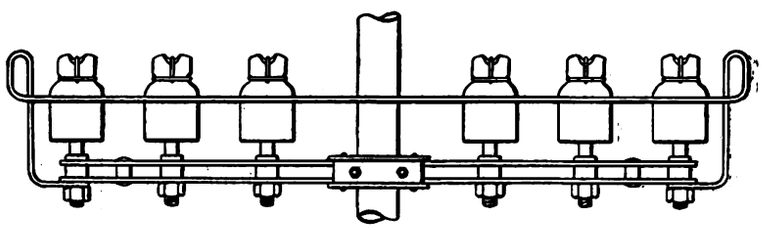

Fig. 4.

The construction of a new device, based on the principle of earthing the falling telephone wire before it touches the tramway conductor, is the direct outcome of an occurrence which happened at Strassburg on August 31st last. During the pulling down of a building two telephone wires were broken. The ends fell on the protecting strips of the working conductor of the tram line, and at the same moment all the enunciators in the telephone exchange dropped. One of the wire ends came in contact with the gutter on the roof of a building, and the gutter going right to earth, lightning-like phenomena were observed in the exchange. Fortunately, the wire leading into the exchange fused, and further damage was thus prevented. The greater part of the tramway current went to earth through the gutter and rain pipe, and not through the exchange.

This occurrence showed us how to construct an effective telephone protector. When a telephone wire breaks, the tramway current must not be conducted to the exchange but to earth. The Allgemeine Elektricitäts Gesellschaft has attained this object by encircling each telephone wire by a wire loop, as shown in Fig. 3. The wire loop is of such a size that even with the strongest wind accidental contact with the telephone wire is impossible. If there are several insulators in a row, a common guard wire can be arranged, as shown in Fig. 4. This arrangement, however, cannot be much recommended in cases where there are a great number of wires close together, as it might then happen that one of the highest wires in falling would get entangled with the lower ones, and consequently would never touch the guard wire. In these cases it is better to run a wire, well earthed, at right angles underneath the telephone wires, which would catch any of the falling wires and earth them. The poles, as well as the guard wire just

† Abstract from the *Elektrotechnische Zeitschrift* of March 26th.

Digitized by Google

mentioned, must be in good connection with the earth, or better still, with the rails.

On February 25th last the Allgemeine Elektricitäts Gesellschaft, in conjunction with Schuckert and Co., made some experiments at Nuremberg with the device just mentioned, and the results obtained were most satisfactory. A 500-volt dynamo was employed and a load of 5 amperes was put on. The machine was protected by fuses and an automatic cut-out. The telephone wires were fitted with wire loops, as shown in Fig. 3, and the telephone instruments were protected by 1-ampere lead fuses.

First Experiment.—The telephone wire was dropped on to the working tramway conductor. At the moment of contact the 10-ampere fuse of the dynamo blew and the automatic cut-out became disengaged. No damage was done to the telephone.

Second Experiment.—At the moment of contact of the wires the 15-ampere dynamo fuse remained intact, but the automatic cut-out acted. The telephone was used during the experiment, and when the wires came in contact, only a cracking noise was heard.

Third Experiment.—The looped guard wire of the telephone conductor was taken away. On letting the telephone wire fall on to the tramway conductor, the telephone fuse went. The instrument, however, remained intact. This proves that lead fuses afford good protection for telephones. The length of the fuse must correspond with the pressure in use.

Fourth Experiment.—The telephone wire was again fitted with the guard loop; and before cutting the wire, an additional piece of wire was joined to it, which, after falling, reached down to the ground. It was absolutely harmless to touch this wire. The safety device acted as in the first and second experiment.

To indicate any interruption of the line at the generating station, and also to show how long these last, the Allgemeine Elektricitäts Gesellschaft arranges parallel to the automatic cut-out five 110-volt glow lamps in series, or one lamp and a sufficient resistance. In case of an earth occurring, the glow lamps will light up at the moment the automatic cut-out acts, and they will continue to burn till the interruption is removed. At the suggestion of Prof. Ulbricht, of Dresden, the lamps were replaced by a needle indicator, which received its current from a small battery instead of the dynamo. When the automatic cut-out acts, the battery circuit is closed, the instrument, as well as a bell which is put into the circuit, indicating the interruption. This arrangement has been made use of at Leipzig.

PUBLIC LIGHTING BY ARC LAMPS.*

BY ANDRÉ BLONDEL.

(Continued from page 793.)

II.—UTILISATION OF THE CONTINUOUS-CURRENT ARC—ORDINARY METHODS.

The ordinary methods, so far as continuous-current arcs are concerned, may be reduced to the two following:—(1) The naked arc is used; the lantern windows or the globes are of ordinary clear glass, and are used simply as a protection against the atmosphere. This is the American system. (2) The arc is fixed in a lantern or a globe of diffusing glass.

The first or second solution is employed according as we wish to reduce the quantity of light lost, or to tone down the brilliancy of the source of light.

Clear Globes.—The naked arc is perfectly satisfactory from a photometric point of view, seeing that, thanks to its natural distribution of light, more than 85 per cent. of the light is sent downwards, and only a loss of about 10 per cent. is experienced in passing through the clear globe; but from the physiological point of view, this system is generally detestable, because of the unendurable brilliancy of the arc, which causes the pupil of the eye to close to its minimum possible size. We have already seen that this effect quite counterbalances any of the photometric benefits of clear glass. It is difficult to understand how American cities can adhere to a system which has such a very fatiguing effect on the eye[27]; we are forced to believe that the public takes no more care of the preservation of its sight than of its stomach. In Europe more attention is paid to this point. In my opinion, naked arcs should be absolutely proscribed for public lighting, except in some exceptional circumstances where the use of very high pillars is justified, as, for instance, in the lighting of ports, &c.[28]. Even under these conditions it would still be desirable to tone down the brilliancy of the sources of light, and to better distribute the light which is concentrated in and about the angle of 45 degrees. I should add also, that with clear glass globes there is about a 10 per cent. reflection of the rays passing through the glass, which sends a far more considerable portion of the light upwards than would be imagined from the photometric curves of the naked arc.

Diffusing Globes.—Diffusing globes are to-day almost exclusively used on European public thoroughfares. They are made of translucent diffusing or semi-diffusing substances. A translucent substance is said to be diffusing when at each point of its surface it transforms an incident ray into a small, conical and very divergent bundle of rays. The globes of this class most used are of a roughened glass or opal (milky throughout), of which alabastrine is the best quality. Globes of this latter description do not allow the source of light to be perceived, but themselves become luminous over the greater portion of their surface, this surface being more extended the softer the source of light (Fig. 30). This is the

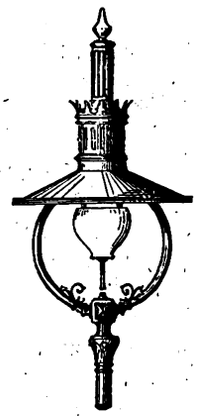

Fig. 29.—Lyre used at Marseilles with Hood Reflector.

characteristic of all diffusion. To diminish the thickness of the opal without weakening the globe, *opaline* globes have been invented. They are formed of a layer of clear glass, coated on the interior with a fine layer of opal. The effect of these globes is shown in Fig. 31, which is a reproduction of a photograph[29]. Such globes allow a great portion of the light to pass directly through them, and therefore are only semi-diffusing. By modifying the thickness of the coating of opal we may pass through all the stages between the clear and the opal globe. To this list of globes should be added that of roughened glass. This is also semi-diffusing, seeing that the luminous point cannot be seen directly through it. The diffusion by it is more or less extended as the roughening is varied, but the

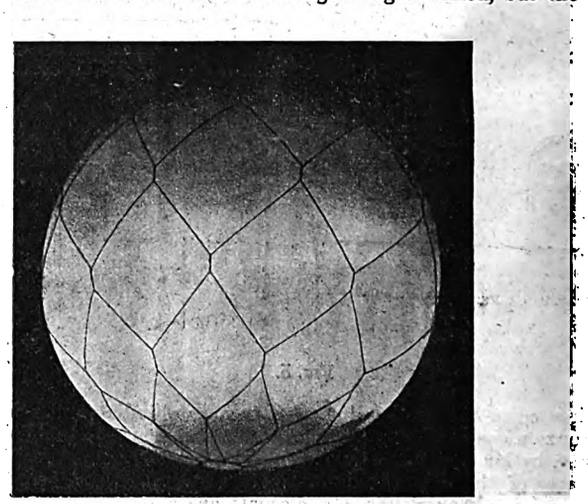

Fig. 30.—Continuous-current Arc in Opal or Alabastrine Globe.

greater part of the light passes through the globe in the same direction as the incident rays. We shall see later how it comes to pass that this globe is at the present time almost out of use.

All globes have the following defects—and in a greater degree as they are more diffusing:—First, they absorb a certain proportion of the light which traverses them. According to measurements I have taken, and to others which I shall quote later, this proportion varies from 20 to 40 per cent. Second, they alter the law of the distribution of light by tending to render the distribution of the rays uniform, seeing that each point of the diffusing surface sends out rays not only in the natural direction of the light, but into all the

* From *La Révue Technique*. Translated by Mr. John Hesketh.

[27] Excepting in the Fifth-avenue at New York, opaline globes are rarely used.

[28] At Havre the pillars are as high as 28 metres, and on the Bavarian railways 18 metres. This is, in my opinion, a mistake, for a considerable loss of light results, and the illumination on a vertical plane, which is very important is much reduced.

[29] These photographs were kindly taken for me by M. A. Laporte, civil engineer, to whom I am extremely indebted.

neighbouring space. If we consider the opal globe as shown in Fig. 32 lighted by a continuous-current arc, A, any point of the globe, *m*, situated below the plane HH′ will emit rays in every direction on the right of *t t′*, which is tangent to the globe, and seeing that the continuous-current arc sends most of its light downwards, a more or less important part of the light will thus be sent upwards towards *t′*, and lost for all practical purposes. It is only right to add that, on the other hand, the rays which are sent downwards in the direction *m t* play a very important part; they light the portion of the roadway close to the lamp post, which without them would be altogether in the dark through the shadow cast by the bottom carbon, the carbon-holder of the lamp, and the lantern itself. It is due to this effect that the refuges on the boulevards are satisfactorily lighted.

The use of diffusers as globes offers, in addition, a certain æsthetic advantage, for the globes appear uniformly luminous on account of the interior reflections (although in reality the continuous-current

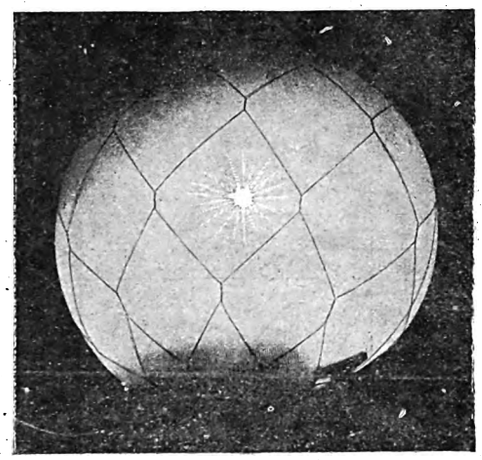

Fig. 31.—Continuous-current Arc in Opaline Globe.

arc sends scarcely any light upwards). This effect is best attained by placing the arc, not in the centre, but in the upper portion of the globe, and almost in the plane of its opening. This arrangement is besides almost necessary in the case of lamps with a long travel. But as the eye instinctively looks for the source of light in the centre of the sphere, it would appear strange for it to be seen right at the top, and therefore from this point of view it is advisable to use globes which do not allow it to be seen. This is all the more necessary when non-focussing lamps, such as the Brush, Thomson-Houston, &c., are used, for nothing can be more deplorable than to see an arc first in one position and then in another. This is, no doubt, responsible for the fact that in France almost all lamps of this class have been abandoned, despite the advantages they possess over focussing lamps on the score of simplicity. It should also be noticed that with opal globes the position of the arc always influences the luminous efficiency.[30]

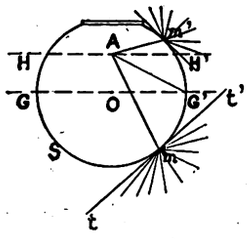

Fig. 32.—Diffusion by Points on an Opal Globe.

If we wish to calculate the reduction of the useful luminous flux produced by the use of the diffusing globe, we should first obtain the loss due to absorption and then that due to diffusion or change in the direction of the rays. The first is arrived at by comparing the total flux emitted by the naked arc with that of the arc in its globe; and the sum of the two losses, by comparing the total flux of the naked arc with the lower hemispherical flux of the arc in the globe. Generally speaking it is these total losses which should be considered in view of the bad use made of reflectors. The ratio of the hemispherical flux utilised, to the total flux, gives the *luminous efficiency* of the globe under consideration.

I intend later to give figures obtained with globes which have been submitted to actual experiments. I will here, however, mention the results obtained by other experimenters. The most classic tests are those of M. Wedding, whose work I have already quoted. The lamps of the Unter-den-Linden are 14-ampere lamps, and the mean of a long series of tests places the mean lower hemispherical candle-power as 1,228 German candles with a naked arc, and as 777, 710, 590 candles with globes of varying degrees of opalescence. The total losses then due to the globe are 40, 45, and 53 per cent., and even these are lower than the reality, because the naked arc was only credited with its hemispherical flux, the light emitted above the horizon, which amounts to at least 10 per cent. of the total light being neglected. Mr. Preece has given the following losses:—with a roughened globe 46·24 per cent.; with an opaline globe 25·18 per cent.[31] I do not see the use of the decimals when we consider the degree of precision of which such measurements are capable. More recently Messrs. Guthrie and F. E. Redhead[32] published the four curves reproduced in Fig. 33;

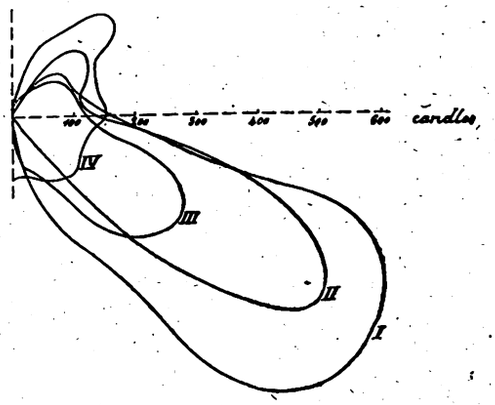

Fig. 33.—Photometric Curves by Messrs. Guthrie and Redhead. I. Naked Arc. II. Clear Globe. III. Roughened Globe. IV. Opal Globe.

which, except curve IV. (which in my opinion is certainly an error) appear accurate. The following are the figures which they obtained in English candles:—

Table III.

—	Naked Arc.	Clear Globe.	Rough'ned Glass Globe.	Opal Globe.
Mean spherical candle-power	319	235	160	144
Mean hemispherical candle-power	450	326	215	138
Percentage value of the mean spherical intensity candle-power	100	53	23	19
Percentage loss	—	47	77	81

The corresponding efficiencies then are 51·3, 33·7, and 21·7 per cent., which I think too low. They and the other figures quoted show that in any case the loss of light is rarely lower than 30 or 40 per cent. and is very often higher[33]; and that, of the 500 to 600 watts supplied to a lamp, at least a third may be considered as thrown away to obtain diffusion.

It is to escape this deplorable state of things that we very often see globes insufficiently opalesced, allowing the arc to be seen almost as plainly as with a clear globe. This is an error, for if we gain a certain quantity of light photometrically speaking, we in reality lose much more in consequence of the physiological effects previously mentioned.[34] Besides which, we have the bad effect of a globe not appearing uniformly lighted. We should therefore consider as bad every opal or opaline globe which allows the arc to be seen, except as a scarcely visible glowing point. In short, diffusing globes of opal give us two evils to choose between—photometric loss and physiological loss. They cannot both be avoided at the

[30] In short, the proportion of light diffused upwards by a point on the surface of the globe is greater as that point is situated higher up the globe. We see how this arises if we examine the effect of the two points *m m′* of the globe, Fig. 32. If a continuous-current arc is placed at the centre O, the most effectively luminous portion of the globe is that portion situated 45deg. below O, while if the arc is placed at A the most illuminating part is near the equator C C′. The quantity of light utilised will evidently be less in the second case than in the first. From this point of view, polygonal lanterns have an advantage on account of the obliquity of the panes.

[31] See *The Electrician*, March 2, 1894, p. 484.

[32] See the *Electrical World*, March 3, 1894, p. 238.

[33] Some writers give lower figures, but this arises from the fact that generally they have measured only the absorption losses, and considered as useful the spherical flux instead of the hemispherical flux. It also happens that very good results are often the result of errors of observation. Again, some so-called opaline globes are so transparent that they produce no diffusion at all.

[34] See *The Electrician*, Vol. XXXVI., November 15, 1895.

Digitized by Google

same time, and the diminution of the ultimate impression on the retina appears never to fall below 50 per cent. We can never recommend the use of roughened glass globe despite its small absorption, for only a very small portion of its surface appears brilliant, the rest being almost obscure, and the effect thus obtained is as disagreeable to the eye as that of a too transparent opaline globe. The roughened glass besides soon gets very dirty under the influence of carbon dust. This last reason alone is sufficient to veto its use in public lighting.[35]

Reflectors.

To utilise the light sent upwards the most natural idea is to employ a reflector. Reflectors of silvered glass being too fragile,[36] and those of metal too difficult to preserve from oxidisation, reflection properly called has almost universally been replaced by diffused reflection by employing white or blue enamelled sheet iron hoods. The use of the latter colour is difficult to explain, for it has a very small reflecting power; while a good white enamel reflects and diffuses about 80 to 90 per cent. of the incident light, which is almost as much as that reflected by a silvered mirror.

Reflectors as a rule are employed in three different ways. In polygonal lanterns they are placed inside under the head of the lantern. To place them outside could not be thought of, for this would make the lanterns, which are already far from elegant, even more ugly. When a suspended globe is used, a reflector is fixed on the upper portion and quite close to the globe, as shown in Fig. 34. In lamps of the lyre type with domes, the reflector is generally saucer-shaped and forms the roof of the dome.

Let us see if these arrangements are of any real utility. We have seen that it is not sufficient to arrange a reflecting surface, even if it be of considerable area, in the neighbourhood of a source

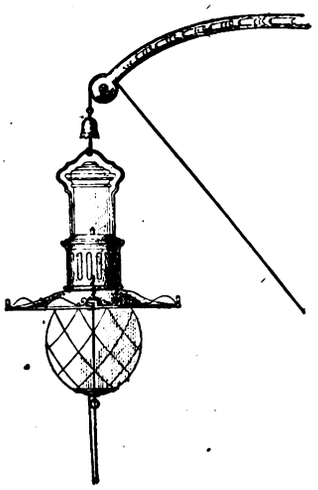

Fig. 34.—Lamp and Reflector used at Munich.

of light. It is necessary that the reflector should play a really active part. We should first make sure that it subtends a large enough solid angle in regard to the source of light, and take care not to confuse the *solid* angle with the *plane* angle subtended by the profile of the reflector. For example, in Fig. 35 there are two reflectors, R_2 and R_1, both of which cut an equal angle ($eoc = gof$) in the vertical plane of the source. But the *solid* angles subtended are proportional to the segments ce and gf. A grave error would, therefore, be committed if we considered only the plane angles. It is also necessary to ascertain from the photometric curve of the source employed, what flux may be received by the solid angle subtended. One source may emit an important portion of its light in one direction while another will send almost none. In the case shown in Fig. 35, the flux received by the reflectors is in the ratio of the two shaded surfaces, $gff'g'$ and $cc'ee'$.

The application of these remarks to the continuous-current arc is very easy. Let us consider, first, the case of a naked arc, or an arc placed in a polygonal lantern. Fig. 35 shows that the flux sent above the horizon is very small relative to the total flux (at most 20 per cent.), and that to reflect it entirely the reflector R must be fixed on the level of the arc. All the light from the arc is then sent on to the panes of the lantern; but if these be opal or opaline, a considerable portion of the rays are lost, as previously pointed out. When globes are used, it is not usual to put the reflector inside, though it can be done, and is done in the case of alternating-current arc lamps. The reflector generally used above the globe (Fig. 36) can play only an almost imaginary part, if given the usual dimensions, for it reflects only the rays sent upwards by a small portion of the globe A C A′ C′ (Fig. 36) and for a point m the useful solid angle subtended by the reflector (limited by m D and normal $m\,h$) is relatively small. For it to play any really useful part, it should be made into a veritable extinguisher, and a very flat one, too, to avoid the reflection in the opposite direction to the one desired. The surface of the reflector should also be kept absolutely clean. If these conditions are not observed, reflectors fixed on globes, suspended or placed in domes, are generally so inefficient that in many cases they are replaced by simple hoods of sheet iron or zinc whose duty is simply to preserve the lamp from the weather, and to stop the rays which would otherwise be troublesome to tenants of neighbouring houses. The hoods at Havre, for instance (Fig. 37) are intended to make the lamps invisible at a distance of 100m. In narrow streets, the tenants of neighbouring houses should be prevented from seeing the arc.

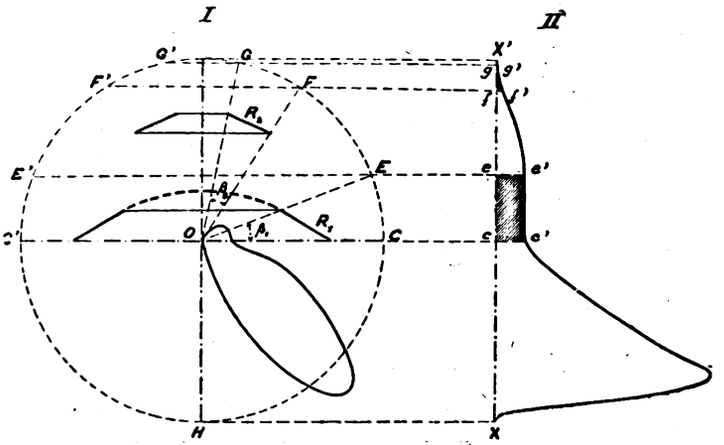

Fig. 35.—Effect of a Reflector According to its Position Relative to the Arc, and According to the Photometric Curve of the Arc. I. Photometric Curve. II. Curve of Flux. R_1. Large Hood Reflector. R_2. Reflector in Cupola or Dome of Lyre.

For this purpose many lyres (such as that at Marseilles, Fig. 29) are fitted with very large hoods. The strangely-shaped hoods used in the United States (Figs. 21, 22, 23) which shade the naked arcs, will also fulfil this object, but they are primarily used as mechanical protection. In Europe, where more artistic taste prevails, hood reflectors for use with the lyres and cupolas have been almost everywhere abandoned, and a small reflector placed in the interior of the cupola (doubtless an imitation of the practice followed with gas lanterns) used instead. But this arrangement can scarcely be of any use; for in the case of a naked arc (Fig. 35) the reflector of the cupola is represented by R_2, and only receives a flux proportionate to the shaded surface $fgf'g'$, which is very insignificant. It is almost the same even for an arc in a globe, for the solid angle subtended always remains extremely small.[37] In short, we see

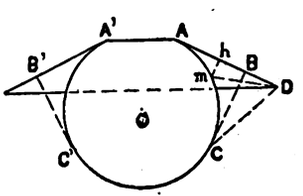

Fig. 36.—Possible Useful Effect of a Reflector fitted to an Opal Globe.

that reflectors usually employed, even admitting that they are very white and carefully kept so, do not, on account of their form, have more than a slight effect; and even this may only be gained by an arrangement which looks absolutely hideous.

Lately attempts have been made to make a better use of reflectors by making them play the leading part in the fittings of lamps. With this end two interesting solutions have been proposed, by Messrs. Hrabowsky and Schuckert. The first, which relies on the use of diffusing reflectors, can be used only for interior lighting; the second seems to have been conceived with the same end, but as it has recently been tried in the public lighting of Munich I will mention it here.[38] The Schuckert apparatus consists of a special

[35] The St. Petersburg lanterns are still fitted with them.

[36] Globes, silvered over part of their surface, have been employed, but have been discarded for many reasons. (1) They only allow the light to be concentrated in a restricted area, which, though advantageous for interior lighting, is useless for public thoroughfares. (2) The silvering rapidly deteriorates with heat, &c. (3) Reflected rays burn away the carbons when focussed upon them. This effect may also be produced by opaline globes, but to a less extent.

[37] In almost all cases, besides, the light regained by the reflector is sent into the immediate neighbourhood of the lamp post, where the light is already superabundant, and is, therefore, useless.

[38] From two interesting articles by Herr Nerz, chief engineer for Messrs. Schuckert (*Elek. Zeit.*, 1894), and Herr Uppenborn, chief engineer to the city of Munich (*Zeit. für Beleuchtungswesen*, January 30, 1895).

Digitized by Google

lantern of large dimensions, as shown in Fig. 38. All the flat panes in it between A B C are made of opaline; those between A E F of silvered glass. The latter send all the rays above O A on to the former, and thus allow nearly all the light to be used and quite diffused; besides which, the great obliquity of the lantern windows makes the quantity of light sent upwards very small indeed. Unfortunately, this arrangement has the effect of concentrating the light in the immediate vicinity of the lantern, to the

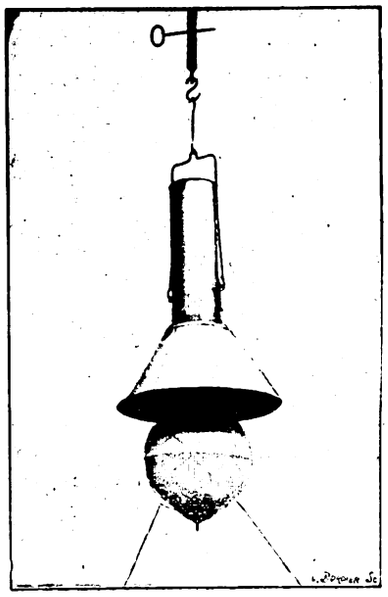

FIG. 37.—Havre Lantern with Hood.

neglect of the other parts. At Munich, on the square in front of the railway station, the experiment was made of placing this apparatus on the top of posts 15 metres high, in lieu of ordinary globes, and of measuring the illumination at various points. It was found that the lighting was less uniform than before, although it was sensibly increased at the foot of the post. It appears, therefore, that though the apparatus may be of use for lighting works, &c.,

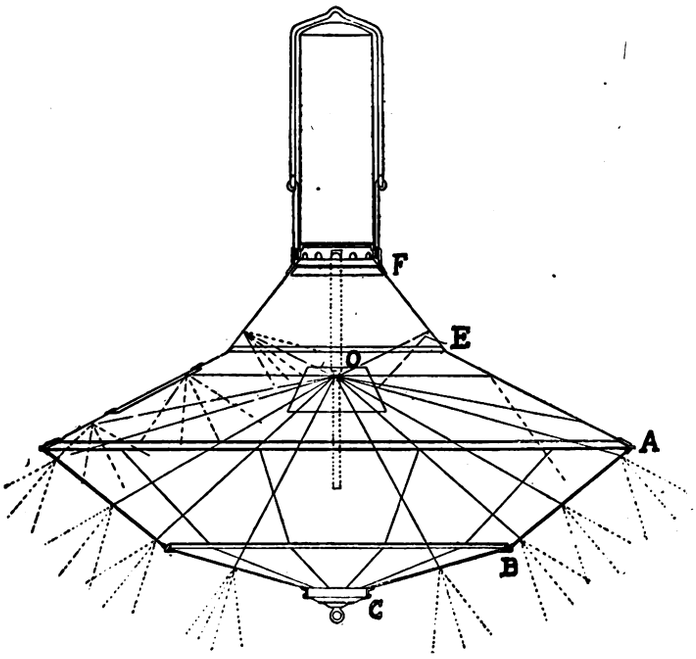

FIG. 38.—Schuckert Reflecting and Diffusing Lantern.

it does not quite meet the requirements of public lighting. The same may, I believe, be said of all other combinations of mirrors and reflectors, &c. They have all the disadvantage of necessitating the use of cumbersome and ugly lanterns. It seems therefore that the problem must be solved in another manner, and we shall see that dioptric methods are able to give better results.

(To be continued).

THE MAGNETIC HOMOGENEITY OF IRON AND STEEL AND THE EFFECT OF ANNEALING.*

BY DR. A. EBELING AND DR. ERICH SCHMIDT.

It has been found during the comparison of various methods of testing iron that different samples of soft wrought iron, and even different portions of the same sample, present distinct differences in magnetic properties, but it has not been clearly established whether the lack of uniformity is inherent or is removable by sufficient annealing. Certain variations in chemical and physical properties have been identified even in small samples of iron, the effect being most marked in wrought metal and much less so in cast iron and cast steel. The following research was undertaken to determine the efficiency of thorough annealing in rendering iron magnetically homogeneous, and to discover in which form it exhibits the greatest uniformity.

In order to test the condition of the metal, short rods were prepared of uniform cross-section and wound with small search coils in the middle, and near the two ends. The rod was magnetised by insertion in a coil of wire placed in a yoke piece of large area, as in Hopkinson's permeameter. Changes in the value of the induction were determined by the currents induced in the search coils due to changes in the magnetising current, and the usual B/H curves were plotted for each of the three positions on the rod.

The result of tests on many samples of wrought and cast iron and steel showed that homogeneity was very rare, a single sample of cast steel being the only specimen in which perfect uniformity was discovered, and the wrought metals exhibiting considerable variations. The effect of long-continued heating was then tried, in order to test the efficiency of this treatment in removing irregularities. The sample, enclosed in an inner tube of porcelain and an outer one of earthenware, was placed in a pottery furnace for many hours. The maximum temperature attained was nearly 1,000°C., and the time occupied in the heating and subsequent cooling was about 50 hours. On testing the metals after the treatment it was found that all the metals were much softened by the prolonged heating, and the hysteresis was considerably reduced. In their uniformity, however, the results differed in the various specimens. The wrought iron was no more homogeneous than before; the wrought steel (wolfram steel) was much improved; the rolled iron was hardly changed, but it was from the first fairly uniform, while the cast steel, which was initially very uniform, showed, after the annealing, a slight variation in its different parts.

It may therefore be concluded (1) that while thorough annealing is beneficial it cannot be relied on for eliminating want of uniformity; (2) that carefully prepared cast metal is more likely to be homogeneous than wrought metal.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, April 17th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Colour Photography," by M. G. Lippmann.

TUESDAY, April 21st.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. The Papers read last week by Messrs. G. H. Hill and G. F. Deacon to be discussed.

WEDNESDAY, April 22nd.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Perfected Photochromoscope and its Colour Photographs," by F. E. Ives.

THURSDAY, April 23rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture (II.): "Recent Chemical Progress," by Prof. Dewar, F.R.S.

FRIDAY, April 24th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read: (1) "Symbolism in Thermodynamics," by R. A. Lehfeldt; (2) "Adjustment of the Kelvin Bridge," by R. Appleyard; (3) "The Effect of Wave-Form on the Alternate-Current Arc," by J. Frith.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "Underground Conductors," by E. Ray and V. Watlington.

*** Particulars of Meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

* Abstract from the *Zeitschrift fur Instrumentenkunde.*

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
- VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free.
- VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 8s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. *[Nearly ready.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. *[In preparation.*

FULL CATALOGUE POST FREE ON APPLICATION.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field: Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; Dr. Heinrich Hertz; Mr. R. E. B. Crompton; William Sturgeon; and Dr. John Hopkinson, F.R.S., have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)

THE METRIC SYSTEM.

A series of articles on the metric system recently appearing in *The Times* has resulted in the usual valuable aftermath, a lengthy correspondence in which this important question is discussed from all possible points of view. Mr. R. KAYE GRAY's letter in Monday's issue calls attention to a curious point in connection with the subject under discussion which has not, so far as we are aware, been previously publicly noted; we allude to the fact, well-known to all residents in France, that even in the home of the system the metric creed is only skin-deep. Penetrate a little below the surface, and *sous*, *toises*, *barriques*, *arpents* and all manner of strange old-world measures are found in daily use.

This phenomenon indeed scarcely amounts to an argument against the adoption of metres, kilogrammes, litres and hectares, any more than the fact that there is an occasional recrudescence of cannibalism among comparatively civilised tribes would justify the abrogation of the laws directed against cannibalism. This obstinate survival of scientifically obsolete units among a people peculiarly exposed to and peculiarly amenable to bureaucratic influence, and whose minds at the time of the first legal institution of the metric system in November, 1801, had been rendered abnormally receptive of novelties by the general upheaval of the previous decade, needs

Digitized by Google

something more than "inborn conservatism" to explain it. Mr. Gray gives all decimalists, metrists and other enthusiasts a clue to this "something more." The most serious point in the whole scheme is, he rightly remarks, "the unnecessary forcing of units on different trades which bear the relation to one another of tens or multiples of ten. The jeweller in exercising his trade finds a carat a very serviceable unit, and no doubt the student of exact sciences finds the decimal relations between the units which exist in the metric system a great advantage; but why this jeweller should insist on the student's adopting the units the jeweller finds best, or *vice versâ*, I fail to see. The weight of a truckload of coals can hardly be conveniently expressed in carats, and as the greatest weight mentioned in the metric system is the myriagramme of approximately 22lb., this system is also unserviceable for dealings in large weights."

The question of the undoubted defects of the metric system is, however, somewhat of an academic one in the present year of grace. With the exception of ourselves, the leading nations of the earth have nominally adopted, or are adopting, a decimal system based upon the metre—a fundamental unit which alas has no longer an absolute basis, but rests on the concrete foundation of the *mètre des archives*. Can we, commercially speaking, afford to hold aloof from this movement? That is the crux. So far we have not been convinced by the arguments on this head adduced by the indefatigable Decimal Association. The statements made as to the trade lost to this country by the use of English weights and measures in English catalogues have always seemed to us, assuming their correctness, more weighty as indictments against the business energy and enterprise of our manufacturers, than as arguments in favour of the adoption in the United Kingdom of a revolutionary system. To the scientific man there can be no question as to the immense superiority of a decimal system. He knows that constant dripping will wear away a stone, and he is equally sure that time, plus Board Schools, will likewise break down the thick crust of custom, and open the eyes of the multitude, at any rate, to the general advantages of the metric system, even if it can still be shown that the system does not here and there exactly square with the particular convenience of a particular trade. To the philosophical statesman, the political economist, and the philanthropist, who are in agreement as to the benefits to all concerned to be derived from the facilitation of international intercourse, any system of weights and measures likely to be generally adopted would commend itself even if it were admittedly inferior in precision or in flexibility to some other system, the use of which was confined to a single race. Hence the adoption or non-adoption by the British Empire of a decimal system based upon the metre rests entirely with the engineer, the manufacturer, and the man in the street; the remaining sections of the community are in complete accord, not merely as to the intrinsic desirability of a decimal system, but as to the irrationality of a compromise which would it is true, indefinitely prolong the life of those picturesque mediæval survivals, the yard and pint pot, but which would forego the innumerable advantages accruing from the adoption of an international common measure. The metric system is both decimal and international. No hybrid device could possess both these properties, and nothing short of this double gain would repay us for a disturbance in which so many of our ancient landmarks would disappear and be lost to the eye of the law, if not to the eye of the man who buys and sells and cares not a jot for logical completeness or an accuracy carried to the second place of decimals.

REVIEWS.

Die Metallcarbide und ihre Verwendung. By Dr. F. B. Ahrens. [London: Williams and Norgate.]

This short monograph forms the first part of a volume dealing with chemical and chemico-technical questions which have lately acquired prominence and have become of general interest. The subjects are necessarily disconnected, and each is dealt with by a writer competent to speak as one having authority.

In the mind of the average technologist the term carbide connotes but two members of the class, viz., silicon carbide (carborundum) and calcium carbide, the raw material from which acetylene is now usually prepared. It must not, however, be overlooked that these are but individuals of a large series of substances, some of which have been known for many years, while others have been but recently prepared. A systematic and sufficiently complete account of them is to be found in this little book, and to speak of them in a review at any length would be superfluous, seeing that the book itself is cheap and accessible. With regard to those which, as we have indicated above, are of immediate industrial importance, somewhat more may be said.

Calcium carbide—whatever may have been ignorantly stated to the contrary—was first prepared by Wöhler in 1862. In 1893 Travers succeeded in making crude calcium carbide by heating a mixture of sodium, calcium chloride and retort-carbon. In 1894 Moissan obtained a good output by fusing lime with carbon in an electric furnace, a process immediately afterwards patented, not by its discoverer but by a person named Bullier. Willson's experiments, made apparently in ignorance of Moissan's discovery, date from the end of 1894, and being noisily bruited abroad caused what Dr. Ahrens appropriately calls "ein volkommenes Carbidfieber." This has gradually died out, doing little harm save to those who found capital for colossal manufacturing enterprises based on fallacious estimates and invalid patents, and the era of steady development of the industrial application of a useful product has now set in. The estimate of the cost of production put forward by the Willson Aluminium Company has an air of unreality; the figures there given are £3 for 908 kilos of calcium carbide or about £8 per ton of acetylene. No reliable data exist for reckoning the electrical energy required for the production of a given weight of carbide, and the figures just quoted appear moreover to be based on the assumption that the carbide produced is of 100 per cent. purity—a result scarcely probable. A comparison may be usefully made with the rates ruling at the works of the Aluminium Company, of Neuhausen. The carbide there produced has an average content of 79 per cent. of CaC_2, and is sold in large lots at 0·4 marks per kilo, whence it follows that 1 ton of acetylene costs about £62. 10s. The discrepancy is striking, and cannot be caused to disappear by allowing any reasonable profit to the Swiss Company. The synthesis of various organic substances using acetylene (from calcium carbide) as a starting point, has been much debated. A favourite subject for discussion is the preparation of alcohol in the manner shown in the following equations:—

(1) $C_2H_2 + H_2 = C_2H_4$
acetylene hydrogen ethylene.

(2) $C_2H_4 + H_2SO_4 = C_2H_5HSO_4$
ethylene sulphuric acid ethylhydrogen sulphate.

(3) $C_2H_5HSO_4 + H_2O = C_2H_5OH + H_2SO_4$
ethylhydrogen sulphate water ethylalcohol sulphuric acid.

Equations (2) and (3), showing the preparation of alcohol from ethylene, are well known, and their smooth fulfilment would allow of the recovery of the sulphuric acid. It is equation (1) which is the crux. Berthelot has stated that he has succeeded in realising it by acting with a reducing agent (zinc) in ammoniacal solution on acetylide of copper. But when calcium carbide was used instead of the copper compound repetition of the experiments by other observers proved wholly fruitless, and even when Berthelot's method was carried out in its entirety, although some hydrogenation of the acetylene certainly took place, yet no alcohol whatever was obtained.

Digitized by Google

Further, taking the cost of calcium carbide at the improbably low price of £4 per ton, assuming the conversion to take place with theoretical accuracy, and ignoring all charges except that of materials for manufacture, the cost of alcohol produced in this manner would be about 7d. per litre, at which price the preparation would be unremunerative.

The author calculates the quantity of electrical energy necessary for the gasification of carbon in the form of acetylene, and from thermo-chemical data arrives at the value 86,540 gram-calories per gram-molecule of acetylene produced. He justifies the conclusion that even putting aside the question of monetary cost of the electrical energy (as distinct from its energy value), acetylene cannot yield as high a percentage of its energy when exploded in a gas engine as does Dowson gas, the deficit being represented by the CO which escapes from the electric furnace in the fundamental reaction $CaO + 3C = CaC_2 + CO$ for the production of calcium carbide.

The prospect of using acetylene for lighting is much better than that of employing it for the purposes mentioned above. When burned under suitable conditions, so as to avoid smoking, 71 litres of acetylene, costing 11·33 pfennig, give 100 c.p. hours, at which estimate its use is cheaper than that of glow lamps, though, of course, dearer than that of the arc; it is even 28·5 per cent. cheaper than ordinary coal gas burned in an Argand lamp. (For portable lamps and similar purposes, liquid acetylene may now be obtained in steel cylinders from the Aktiengesellschaft für Chemische Industrie, of Mannheim.) In spite of these excellent results, there is no likelihood of acetylene replacing coal gas (having regard to the extensive use of the incandescent gas burner), or of being adopted for enriching coal gas (seeing that benzene is cheap and efficient for that purpose), but it may well be used for isolated and locomotive lighting. One incidental but important advantage possessed by acetylene as a lighting agent depends on the fact that for a given output of light it evolves a smaller quantity of heat and carbon dioxide than does any ordinary illuminant. Dr. Ahrens gives a useful table comparing various factors in the practical efficiency of numerous lighting methods which is well worthy of study.

A few words must suffice for notice of what is said in this little book about silicon carbide. The mode of production has been frequently described and need not be repeated. It is interesting to note, however, that when clay is used instead of pure silica the product contains alumina, ferric oxide and apparently silica as well as silicon carbide; it is solely by the use of approximately pure raw materials that a product with a composition corresponding nearly with that indicated by the formula SiC can be obtained. Grinding and polishing wheels of carborundum are made by mixing the small crystals, as obtained after washing and grading the furnace product, with a fusible agglutinate, moulding the mass into the required shape and heating to the sintering point of the binding material.

At the end of the book the author reviews Moissan's attempts to prepare the diamond from non-crystalline carbon, and adduces good evidence for regarding the product obtained by the French chemist as a silicon carbide extremely rich in carbon, rather than a pure crystalline carbon. The matter is in need of further investigation.

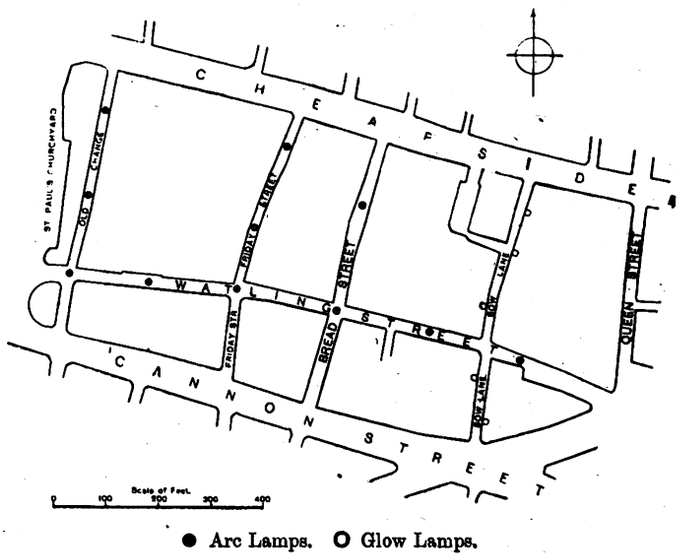
Our opinion of the brochure may be stated very briefly. It is an admirable compendium of many facts hitherto widely scattered, and will save much labour and many weary searches on the part of chemists and electricians interested in certain novel and growing industries.

Les Rayons-X et la Photographie a Travers les Corps Opaques.
By Ch. Ed. Guillaume. (Paris: Gauthier-Villars et Fils.)

In a well-printed well-arranged little brochure of some 124 pages M. Guillaume not only sums up the most discoveries in connection with Röntgen rays, and gives his readers the inevitable collection of radiographs, but he also provides a much-needed historical *résumé* of the work done on electrical phenomena in rarefied gases, and an introductory section linking the latest phenomena with current physical theories. The book exhibits but few traces of the haste in which it must have been got together.

THE ELECTRIC LIGHTING OF THE SIDE STREETS OF THE CITY.

Those who have been courageous enough to undertake the defence of the alternate-current arc have, when confronted with the tell-tale records of the photometer, invariably brought forward the argument that no sensible man expects a mechanism to do its best unless it is worked in the best possible manner; when alternate-current arcs have been supplied with carbons of proper diameter and suitable quality and with the correct number of volts and amperes, it will be time enough, they say, to dogmatically assert that the alternate-current arc is hopelessly inferior to its continuous-current congener. This is a safe and by no means unreasonable attitude. The interesting and exhaustive experiments, however, which are about to be undertaken by the City Commissioners of Sewers in conjunction with the City of London Electric Lighting Company, with a view of ascertaining the cheapest and most effective way of lighting the alleys and side streets of the City, ought, if the contemplated programme be completely carried out, to settle this thorny question once and for all. In the area bounded on the north by Cheapside, on the south by Cannon-street, on the east by Queen-street, and on the west by St. Paul's-churchyard, there will shortly be at work 11 arcs and 5 glow-lamps. The number is indeed small, but it is sufficient for the purpose. The arc lamps will at first be supplied



● Arc Lamps. O Glow Lamps.

with alternate-currents, each one from a separate transformer, and measurements will be made of the useful illumination. It is proposed to supply them with about 7 amperes and to use globes, the lower half of which will be obscured, the top half remaining clear. Some of these lamps will be slung from girders or rods, others from brackets. Some of these are substantial-looking cambered girders, others slender, not to say "skimpy" looking straight rods, supporting the lamp at about 20ft. from the road way. All of them will be supplied with combined traversing and hoisting gear, so arranged that by the time the lamp is vertically over the pavement it will have been lowered to a suitable height for trimming. When the luminous output of these lamps with alternating-current has been photometered they will be supplied with continuous current, and the photometric measurements will be repeated. As will be seen by the sketch map (Fig. 1) the 11 arc lamps will be distributed along Watling-street, Old Change, Friday-street and Bread-street. At the same time five 200-watt glow lamps, run straight off the supply mains, are to be brought into use. The first three, which one encounters on entering Bow-lane from Cheapside, are suspended from substantial-looking gilded wrought-iron brackets, designed and made by W. B. Reynolds, the remaining two being suspended from more ordinary looking supports. The reflectors of the first three are of a peculiarly curved dish-shape

Digitized by Google

pattern. They look effective, and should, prove optically superior to the common cone-shaped reflectors by which glow-lamps are generally well-nigh extinguished. The merits of the Frédureau projector globe are also to be tested in Bow-lane.

THE DIRECT CONNECTION OF ELECTRIC MOTORS WITH MACHINES OF VARIOUS TYPES.*

BY WILLIAM BAXTER, JUN.

The efficiency of transmission by shafting is less with light running machinery than with heavy; but lightness of machinery is not the only factor that determines the efficiency. The continuous or intermittent use of power has as much to do with the subject, if not more, than anything else. If a machine absorbs a large amount of power when in operation, it must be driven by heavy shafting. If it is in constant use the loss of energy in shafting and belts will be small, but if not in constant use this loss may become very great, and will depend wholly upon the ratio between the time when work is being done, and when the machine is standing idle. From a consideration of this fact we can see that under certain conditions of intermittent use the loss in operating heavy machinery by shafting may be very much greater than with the lightest machinery, especially if the latter is kept in constant motion.

The field in which the direct connection of motors with machines would make the poorest showing would be that when the power required is not very small and the work continuous. On the other hand, the best results would be obtained with machines requiring a large amount of power while in operation, but only in use for short periods of time, with long intervals of rest. In the former class may be mentioned cotton and woollen mill machinery, and all kinds of automatic machinery used in manufacturing processes. Among the latter are printing presses, paper cutters, embossing machines and, in fact, most of the machinery used in this line of industry, also wood and metal working machinery of all kinds.

We cannot say that the work performed by machines of the classes just named is always of an intermittent character, but it is generally so. Printing presses, in some cases, are used continuously, but as a rule their work is intermittent, and they are frequently stopped for periods some times of several hours' duration, owing to the fact that the number of copies required of any one forme is seldom sufficient to keep them in operation for any great length of time. Even when the work on hand is enough to keep all the presses in an establishment in constant use, the number of hours when power is used is not a very large proportion of the whole. It requires a considerable length of time to remove the old formes and put new ones in place. To clean the rollers, try the press, and examine the proof copies, and to make sure that everything is in proper adjustment before starting to run off the edition. In most printing establishments it is not uncommon to see half the presses idle at a time. It is evident, therefore, that in this line of work the energy lost by shafting is a large percentage of the whole, so that as far as efficiency is concerned this is a very favourable field for the direct connection of motors.

What has been said in relation to the work of printing presses not being always intermittent also applies to wood and metal working machines. Thus, for example, we may consider the case of a lathe used for turning shafting. In such a case the use of power would be almost continuous, because it would require a considerable length of time to finish one piece, and the work of removing this and putting in place another piece would only require a few minutes, owing to the fact that the work is of a routine character, and all the appliances for setting and holding the work in place are made with a view to saving labour in manipulation. But if the same lathe is used for general work the results will be very different. More time will be required to set and secure the work in place, because special means to accomplish this end will have to be used in almost every case. After the work is properly set and secured, and the latter is set in motion, there will be a considerable time lost, from the fact that frequent stoppages will be made to examine the progress made, and to take measurements, and perhaps to make comparisons with other parts of the apparatus to which the piece may belong. In some cases the time consumed in cutting away the metal of a casting or forging is very small compared to that required to set the work and make the necessary examinations and measurements as the cutting progresses.

These few illustrations are sufficient to show that in operating machines by the ordinary method of shafting and belting the loss of energy is greatest where the work is of such character that the machines do not run continuously, and that the very lowest efficiency is attained in cases where, in addition to the work being intermittent, the machinery is light, and, therefore, the transmission of energy per unit of length of shaft very small. On the other hand, the highest efficiency is reached in that class of work where the machinery is in continuous use, or nearly so, and where length of shafting is greatest.

From these facts we must conclude that in the direct connection of motors with machines we could obtain the best results in the efficient use of energy by selecting machines that require a small amount of power for their operation, and are used for a class of work in which the intervals of rest are numerous and of considerable duration.

It is somewhat unfortunate that these are the conditions that will enable the direct connection of motors to give the best results in point of efficiency, because, as will be presently shown, the class of machines in which these conditions obtain are generally those in which the combination would compel the motor to undergo the severest test. But no one need be discouraged on this account. Electric motors, when properly constructed, are wonderfully enduring machines, and have been accustomed to hard knocks since the days of their infancy. The ideal condition of running for a motor, that is, for ease of task, would be when it could be started in the morning and be kept in motion with a constant load all day long. But these conditions do not obtain in any of the direct connections so far made, with the exception of fan blowers and pumps, and are hardly to be expected in any of the work of the future. The work that is now being done by direct-connected motors imposes the severest conditions that are possible. It is difficult to conceive of any kind of work that would impose a greater strain on motors and the operating apparatus used therewith, than that to which they are subjected in railway and elevator service. Such motors when starting under a heavy load are subjected to a rush of current that almost amounts to a short circuit; that is, if they are geared for a high velocity, and therefore are compelled to set the mass in motion without any undue loss of time. Under these conditions the strain on the insulation is very great, and it would soon break down unless of the most substantial construction. But this is one of the minor troubles which is easily guarded against. The effect on the commutator is far more difficult to contend with. But absolutely sparkless running in such a motor is not possible, because the flashing at the instant of starting roughens the surface of the commutator over a considerable arc, and as the motor seldom starts with the armature in the same position, each start roughens a new spot, and finally the whole surface becomes rough. If the starts were at long intervals apart, the action of the brushes during the long intervening run would smoothe up these spots, but as the starts are very frequent no such results can be effected. Therefore the surface of the commutator remains constantly rough, and consequently the brushes spark continuously. Yet a motor that would act this way, when subject to the severe test imposed upon it in railway or elevator work, would in all probability run sparkless if in continuous motion and subject to the ordinary variations in load that stationary motors have to contend with. It will therefore be seen that for this class of work a motor must be proportioned with much greater accuracy, to avoid sparking, than is required in machines subject to the ordinary conditions encountered in stationary work.

If the question of the efficient use of power were to decide whether the combination of a motor with any particular machine would be desirable, the prospects in this line of work would not be very bright, particularly if the cost of maintenance were to be brought in to off set the saving in power. The cost of power in most manufacturing establishments is but a small percentage of the total expenses, therefore the saving of a portion of this expense would not affect the economy of operation to any very great extent; and if this slight saving were to be reduced by the increase in cost of repairs, as well as first cost—if these should be against the motor—the chances are that, in most cases, the advantages of the new method would not be enough to justify its adoption. But other considerations as well as economy have a bearing on the case. Among these may be mentioned that in many establishments the belts and shafting are in the way, and interfere with the proper handling of the work. These conditions exist in large iron and other metal manufactories, where heavy work is handled, and where overhead travelling cranes are almost indispensable. These cannot be used if line shafts and belts are in the way. This difficulty is overcome in many places by running a line of shafting against the wall on each side of the shop; but if the building is of any considerable width it will be found that in most cases there is more unoccupied floor space along the centre than is really required, and that some of it could be utilised if power could be conveyed to tools located thereon without interfering with the crane. In several shops of this kind experiments are being tried with lathes, planers' boring mills, and other tools operated by motors. There can be but little doubt that these experiments will be successful, and in the course of time a large number of direct-connected iron-working tools will be used in establishments of this kind.

A considerable work is being done at the present time in the direct connection of motors with printing presses of various kinds.

* Abstract from the *Electrical World* of New York.

Digitized by Google

Perhaps one of the largest plants of this class, if indeed not the largest in the world, is that of the American Book Company, located in the new building erected on the site of the old University Building, on the east side of Washington-square, New York. This plant, when completed, will consist of nearly a hundred machines, each provided with a direct-connected motor, with the exception of some of the smallest machines, which are driven in groups of four or six to one motor.

What the advantages of direct-connected machines in printing establishments may be, the writer would not undertake to state, not being familiar with the requirements in that line of work, but that the advantages must be quite apparent is evident from the fact that those who know what the requirements are have been sufficiently impressed with the advantages to be derived to induce them to try the experiment on such a large scale.

There is another field, however, for the electric motor in manufacturing establishments, in which the advantages to be derived from its use are more apparent than those that may be claimed for the system of direct connection with each machine. This field is that of operating each line of shafting or system of shafting by an independent motor. It frequently happens that the construction of a building is such that it is not possible to drive each line of shafting from the main line, and that the only way in which the power can be transmitted is from one shaft to the other, and so on through to the last. With such an arrangement one line of shafting could not be used without driving all the other lines, and this, in most cases, would be a decided objection. But if each line were driven by a separate motor, they would each be independent of all the others, and any one could be used without any reference to the others. In other cases the direction of the lines of shafting is not always the same, and motion is transmitted from one to the other by means of quarter-turn belts. In such cases, especially if the power transmitted is large, a motor would give by far more satisfactory results.

In very large works, where there are numerous buildings running in different directions and some distance from each other, it would be found that very good results would be obtained by generating all the power required for the entire establishment in one central power-house, and transmitting it to the various buildings, where it would be utilised through the agency of motors. In this arrangement, if each line of shafting were driven by a separate motor, it would be possible to run any part of any building, or the whole, so that anything from a single line of shafting up to the entire plant could be used, if desired.

TELEPHONE EXCHANGES AND THEIR WORKING.*

BY DANE SINCLAIR.

In introducing this subject I find that, to give you anything like a clear idea of the working of telephone exchanges as they exist in this country, it will be necessary for me to refer to a few fundamental principles underlying all telephone exchange work, which, however, have been previously explained in journals, text-books and elsewhere.

In all telephone systems there are three branches into which they may naturally be divided, viz.—

1. The line wires connecting subscribers' offices to exchanges;
2. The instruments in subscribers' offices; and
3. The switchboards in the exchanges.

With reference to the lines, it is not my intention here to say much in regard to them, although, indeed, the lines now used for telephonic purposes differ very greatly from those formerly used for telegraphic work. It was not until the introduction of the teelphone that such subjects as the static capacity and self-induction of lines received so much attention in other than submarine telegraph work. In telephone work, however, these points are of the very highest importance, and necessitate a large amount of attention. We have arrangements working on our telephone lines which, at first sight, would have appeared to the telegraph engineer to be the worst that could possibly be devised. I have made some experiments on telephone lines, and, under certain conditions, have obtained better speaking results over a line 40 miles in length, on which there was a series of earths, or leakages, than could have been obtained with a well-insulated line. The same applies to metallic circuits, but in this case the leakage is from the out-going wire to the return. This subject, although interesting, is, however, outside the scope of my present Paper.

Broadly speaking, all the calling instruments now used in this country in subscribers' offices are those known as the magneto pattern, and there is fitted along with each a transmitter, battery, and receiver, the whole forming a complete set.

It is, however, the switchboards at the exchanges that I wish specially to bring before your notice to-night.

* Paper read before the Institution of Electrical Engineers March 25th.

The diagram at Fig. 1 shows the connections which, with certain modifications, are made on all kinds of switchboards. The apparatus includes a line jack, marked J, and an indicator, marked I, through both of which the circuit passes either to a general earth wire, or, in the case of metallic circuits, to a return wire. I may explain that what is called a "jack" is that part of the apparatus into which the connecting plug is inserted. When any two lines are to be connected together, two of these plugs are inserted into

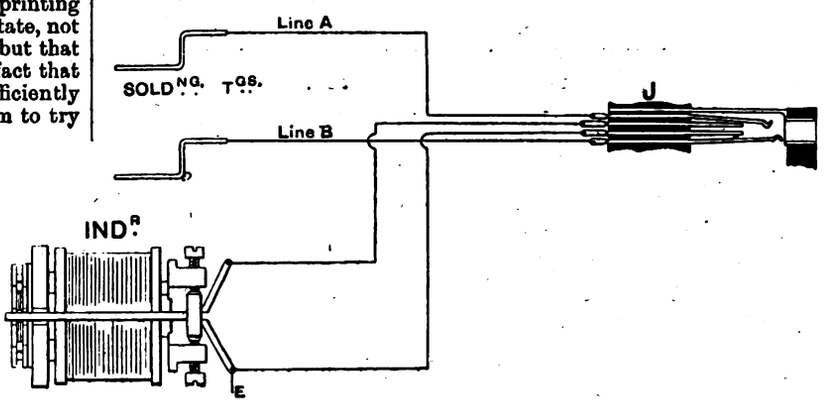


FIG. 1.—Line Connections of a Double Cord Board.

the two jacks of the lines concerned, the plugs being connected together by a flexible conducting cord.

It is our usual practice in this country for small exchanges (of, say, under 200 lines) to make up the switchboard in sections of 50 lines. The drawing at Fig. 2 shows the type of section which has been adopted by the National Telephone Company for general use

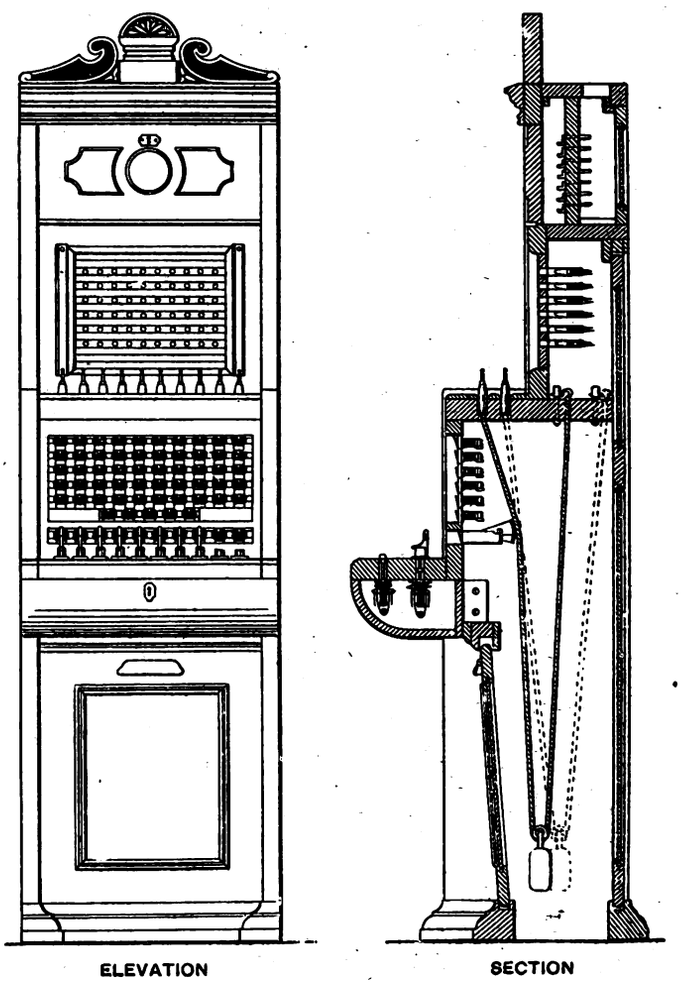

FIG. 2.—50-Line Switchboard. Double Cord Metallic Circuit.

in these small exchanges. In its main principles it is the same as other small standard boards, but special attention has been given to the details; facilities have been provided for connecting the line wires to the switchboard, and all the working parts have been covered so as to exclude dust as much as possible.

Digitized by Google

A further reference to Fig. 1 will show that here, as before described, the line passes through the jack and indicator, and back by the return wire. Cords, similar to the one already mentioned, are fitted on a shelf, each cord having a pulley and weight to bring it back to its proper place when out of use. A ring-off indicator is also provided, which can be put in bridge across the cord by means of the key designed for that purpose. This key is shown at Fig. 3, and by it the operator can also throw her telephone into or out of circuit as required. A separate pair of keys is provided to enable the operator to ring on either of the lines she is connecting. The ringing current is, as a rule, produced by a small generator driven by an electric or other motor. These listening keys and ringing keys are now universally used by the National Telephone Company, and are all of the standard patterns shown.

When a subscriber turns the handle of his generator the shutter of his indicator in the exchange drops and shows his number. The operator then inserts one of the plugs of a double cord into the jack belonging to this line, and asks the subscriber what he wants. When this information is received the operator inserts the plug at the other end of the cord into the jack of the line wanted, and completes the operation by turning the lever of her key, which cuts her telephone out of circuit and brings in the ring-off indicator. This indicator, as before mentioned, is now connected across the line in bridge in the case of metallic circuits, or tapped to earth in the case of single wires. This indicator is of a special type, being wound to a resistance of 1,000 ohms, and placed inside a tube of soft iron, so as to give it large self-induction and cause great impedance to the passage of telephone currents, which are, of course, of high frequency. The object of this indicator is to show the operator when subscribers have finished their conversation. When this signal is given to the operator the plugs are withdrawn and everything restored to its normal condition.

As the subscribers' indicators are cut out of circuit when their lines are connected as described above, they are of the ordinary type, and are wound to a resistance of 100 ohms.

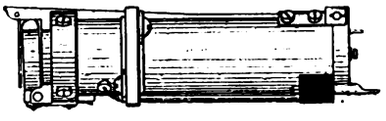

FIG. 3A.—S. R^{G}. Indicator.

In addition to the type of board already mentioned, shown at Fig. 2, we have used in this country very largely, for small exchanges and for private installations, a class of switchboard known as the "single-cord" board. In this pattern of board a cord and plug are provided for each line, and, as shown on the drawing (Fig. 4), the lines come to the outer springs of the jacks, and, without breaking, pass to the cord and terminate in the plug. In addition to this, a high-resistance indicator, of the same type as the ring-off indicator previously described, is provided for each line. To make a connection, the plug of the line of the calling subscriber is inserted into the jack of the line wanted, leaving the indicator of the first line in circuit, and, as will be seen in Fig. 4, the indicator of the second line is cut out of circuit. For working this class of board, the operating instrument is provided with a plug for answering the calling subscriber, and for ringing the subscriber wanted.

It will be readily understood from what has been said that, as exchanges increase in size, the switchboards become too large for the operators to be able to reach to make all the connections. In the earlier days, wires were run between the various sections of the board for the purpose of connecting the different groups of subscribers' wires together. At this point commenced the difficulties of telephone exchange work, because there was no certain method of showing to the operators in the exchange when any subscriber's line was engaged, and also because the first operator had not complete control of the connection, and consequently it was liable to be interfered with by the second operator. In practice this became a very serious trouble. A remedy was found by our friends on the other side of the Atlantic, where they had to deal with the question of large exchanges earlier than we in this country. To overcome the difficulty they invented what is known as the "multiple" board, the possession of patents for which must have given the owners very considerable satisfaction, as well as yielded them enormous profits.

In this connection I may mention that the multiple system was independently invented by an employé of the United Telephone Company, but subsequently to the date of the American patent.

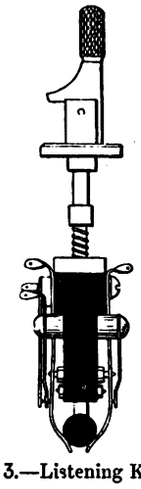

FIG. 3.—Listening Key.

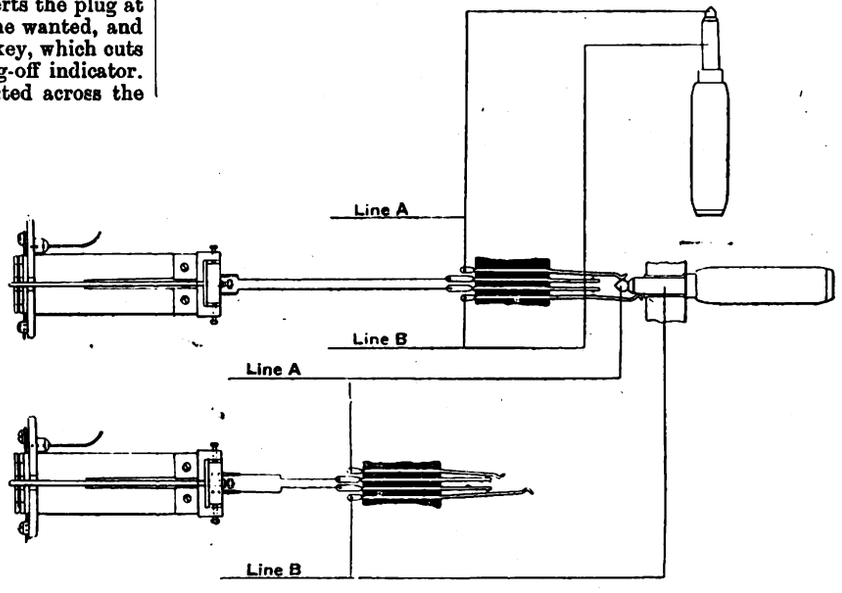

FIG. 4—Line Connections of a Single-Cord Board.

The multiple switch-boards used generally in this country are made up of the required number of sections, each containing all the apparatus necessary for 200 lines. Each section is 6ft. 6in. in length, and is subdivided for four operators, each having 12 pairs of connecting cords, with the usual equipment of listening and ringing keys of the type shown at Figs. 3 and 5. In addition to the full equipment of apparatus necessary for 200 lines, each section is also fitted with jacks, through which all the lines in the exchange pass.

On this principle the number of jacks necessary in an exchange increases in an amazing manner. For instance, an exchange with 400 subscribers' wires would require only 800 line jacks—*i.e.*, the 400 lines in the exchange would come to jacks on section No. 1, and be repeated on section No. 2; but, if we consider an exchange of 5,000 subscribers' lines under similar conditions, we find that there would be 25 sections of 200 lines each. As in the case of the two sections mentioned, the line jacks would be repeated on each of the 25 sections (5,000 on each), making a total of 125,000 line jacks. In practice every exchange is provided also with junction wires to other exchanges, and many of them with trunk wires to other towns.

The junction wires are divided into two approximately equal groups, one carrying the outgoing and the other the incoming traffic. To render the outgoing junctions accessible to all the operators, they are, like the subscribers' lines, multiplied on every section. Incoming junctions do not require to be multiplied, but special sections are provided for working them, and these also contain a multiple of all the subscribers' lines. As it is found in practice that an operator cannot attend to more than 25 of these junction lines, each section, with four operators, will accommodate 100 junction lines.

In an exchange of 5,000 subscribers, forming part of a system similar to that existing in London, there would be 1,000 junction wires, say 500 outgoing and 500 incoming. The latter would necessitate the provision of five extra sections, thus bringing the total to 30 sections, whilst the former would involve the use of 500 additional jacks on each section, making the total number of jacks 165,000.

It will thus be seen that a multiple board for 5,000 subscribers' lines is a huge electrical equipment. The number of soldered joints

Digitized by Google

on such a switchboard, in connection with the jacks alone, is nearly a million, and the total length of wire is between 1,500 and 1,600 miles.

The largest switchboard we have in this country is one which has been provided for taking the total number of jacks required for 8,400 subscribers' lines—*i.e.*, including junctions, 9,000 line jacks on each section—and for such an exchange, fitted on the ordinary multiple system, there would be required a total of 432,000 line jacks; so that, while we have only increased the number of subscribers' lines from 5,000 to 8,400 (*i.e.*, 68 per cent.), we have increased the number of multiple jacks required from 165,000 to 432,000, or 162 per cent.

In Fig. 5, A, B, C, D, &c., represent a subscriber's line passing through separate sections of a switchboard. The wires come to the outer springs of jack A, and pass from the inner contacts to the outer springs of jack B, and so through all the sections. If the number of this subscriber's line is between 1 and 200,

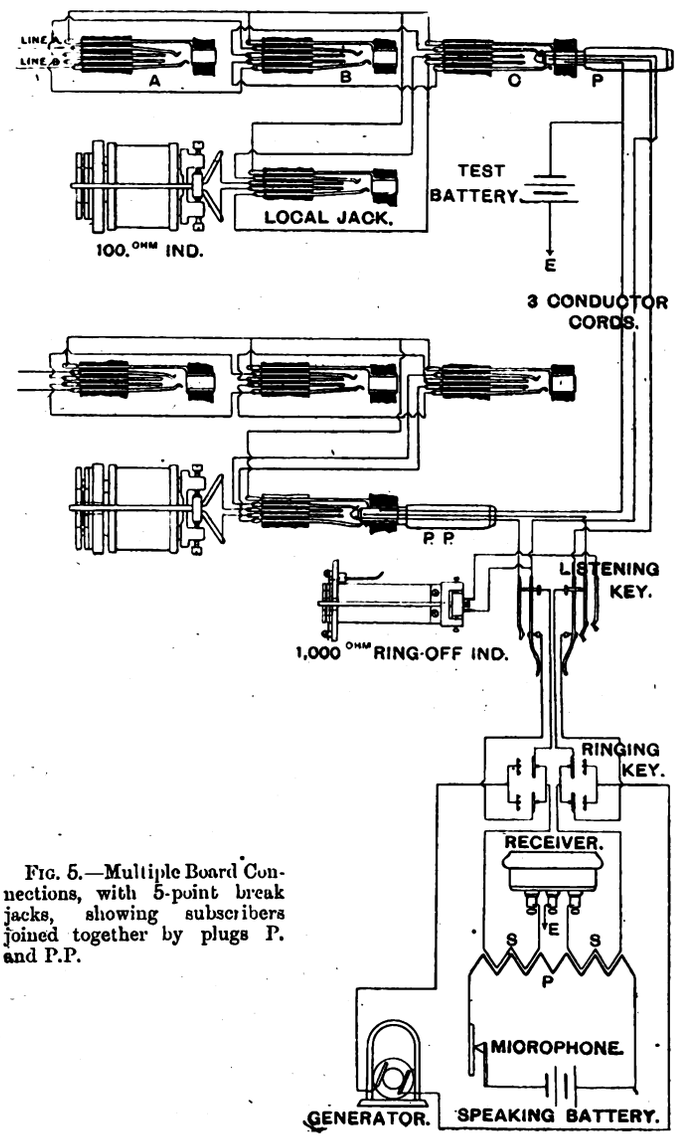

FIG. 5.—Multiple Board Connections, with 5-point break jacks, showing subscribers joined together by plugs P. and P.P.

the wires, after passing through all the sections, would return to section A, pass through the local jack, and end in the indicator. A third wire in connection with the barrels of the jacks is also carried through all the sections, and is normally an insulated wire. This is the test wire by means of which an operator ascertains whether or not the line wanted is engaged at any other section.

When an operator replies to a subscriber she inserts a plug into the jack of his line. The tip and ring of the plug connect to the line wires, and the sleeve joins the barrel of the jack to a battery, the other side of which is connected to earth or a common return. To complete the connection the jack of the line wanted is similarly treated. Should either of those subscribers now be asked for at another section of the board, the operator there would touch the barrel of that subscriber's jack with the tip of the plug with which she proposed to make the connection, when a current would pass from the test wire through her telephone, causing a click, and so advising her that the line was engaged.

The spring jacks are made up in strips of 20, mounted on two parallel pieces of vulcanite 1⅝in. apart. I submit a sample strip of these jacks. The front piece is 11½in. × ½in. × ½in., and the distance from centre to centre of the jacks is ½in. The back part is slotted, and the springs which fit into these slots are shouldered; so that they cannot be forced out of position by the plug. Each jack has two long springs to which the line wires are connected, and these grip the plug. These springs rest on shorter springs (both being provided with platinum contacts) which are connected to the corresponding jacks in the succeeding sections of the board, and, lastly, to the local jack and indicator. A strip of metal is connected to the barrel of the jack, and is carried to the back as a soldering tag, and to this the test wire is attached. These strips are secured to stiles in the upper portion of the board by special fasteners, which allow of any strip being readily withdrawn for repairing purposes.

I have here a sample showing how one row of jacks is connected by cable with the corresponding row in the succeeding section of the multiple.

The wires are carried throughout the switchboard in 63-wire cables, each cable serving 20 subscribers or one strip of jacks, and having three spare wires to provide for breakages. The copper conductor is No. 22 gauge, insulated with rubber and paraffined cotton. The wires are laid up in threes—two line wires and one test wire for each subscriber. Seven such strands are twisted together, and three such groups of wires are laid side by side and covered with cotton braiding saturated with paraffin. The size of the finished cable is about ⅞in. by ⅜in. inch.

The listening and ringing keys, and their connections, are the same as those shown with reference to small boards.

The operator's telephone has received considerable attention of late years. It was, until lately, the practice to suspend the transmitter from the top of the board, and the receiver had to be held to the ear by hand. Now the transmitter is fitted in an aluminium case, which is fixed to a light breast-plate of the same metal, and this is suspended round the neck of the operator, so that the mouthpiece is always conveniently placed for talking into. The receiver is also made up in a light form, and kept against the operator's ear by metallic springs or an elastic band. By the use of these instruments both her hands are left free for operating. The induction coil of the transmitter and the coils of the receiver are differentially wound, and the centre point of the latter coils is joined to earth to allow of the "engaged" test being obtained, and of the operator working earth circuit and metallic circuit lines on the same board indiscriminately. The earth being connected to the centre of the differentially-wound coil has no detrimental effect on a metallic circuit line.

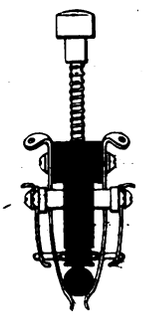

FIG. 5A.—Ringing Key.

The boards just described are complete metallic circuit boards, and are used very extensively in this country. They work satisfactorily on earth circuits, and, if necessary, may be employed on earth circuit systems as transition boards. When on this system metallic circuits are joined to other metallic circuits they form a perfect metallic loop, but when joined to earth circuits one side of the metallic circuit is earthed at the exchange; the circuit so formed being but little better than a line with earth return throughout, the second line simply acting as a screen to lessen induction. All these connections are made in an exactly similar manner, the operator not having to distinguish between single and metallic circuits.

The problems in switchboard work have always been, firstly, how quickly can a connection be made? and secondly, how can efficiency be best obtained?

With reference to the first, the desired end is attained by reducing to a minimum the number of movements necessary, and making those movements as easy as possible.

With reference to the second condition, in the earlier boards it was usual to leave the two line indicators in circuit when the lines

Digitized by Google

were joined together; and the first step taken to improve this was to cut one out, or to cut out both line indicators, substituting a special indicator for the purpose of receiving the subscriber's clearing signal. The electromagnet of this indicator was, however, directly in the circuit. It was observed that any such electromagnet in the line circuit cut down the talking very considerably, one indicator having probably as much effect in reducing the efficiency of the speaking as 50 miles of an ordinary aerial line. The next step was to increase the resistance and self-induction of the ring-off indicator, and place it in shunt across the two lines of a metallic circuit, or as a tap to earth on single lines. It had also been found that trouble was sometimes caused by dirty contacts in the spring jacks. To obviate this difficulty some of the later boards have all the spring jacks wired in parallel, and the two line indicators, which are of special pattern, left in shunt. This system is sometimes called the "self-restoring" and sometimes the "branching" system; but, as the latter name had been correctly applied to other systems which had preceded it, and of which this is an extension, I prefer to use the former term.

In this system the work of the operator is lessened, inasmuch as the shutter of the indicator is automatically restored in answering the subscriber. This allows the indicators to be placed at the top of the boards, where space is not so valuable, and the spring jacks to be placed lower, thus bringing a much larger number within easy reach of the operator, and materially increasing the ultimate capacity of the board. The general arrangement of this class of board is much the same as that previously described, except that, as just mentioned, the indicators are placed over instead of under the spring jacks. The apparatus, however, is somewhat different. The springs of the jacks are let into a solid slab of vulcanite. There are three of these springs, two being of equal length, and one shorter. The front of the slab of vulcanite carries two bushes, one behind, but insulated from, the other. The line wires are continuous throughout the exchange, ending at the subscriber's indicator. Branches are brought from these at each section, one to the short spring and the other to the inner bush of the jack. The two springs of equal length a rejoined, one to a common battery wire running round the exchange and the other to the corresponding springs of all the jacks in the same line, and, finally, also to the indicator. This latter spring is also in metallic contact with the front bush of its own jack. When a plug is inserted in a jack, the tip comes into contact with one line through the short spring; the sleeve, through the barrel, with the other line; and the two springs of equal length are connected by an insulated metallic ring between the tip and the sleeve. The tip and the sleeve are joined to the two conductors in the flexible cord used for connecting two subscribers.

The indicator consists of two separate single-coil electro-magnets, both sheathed with iron, and fixed one in front of the other. To the back one, which has a resistance of 1,000 ohms, the line wires are attached. The front one, which has a resistance of 45 ohms, is connected on one side to the test circuit, and on the other to earth or to the common return of the restoring battery.

When a subscriber calls, a heavy armature pivotted in front of the restoring cell is released, and, falling forward a short distance, lifts a light aluminium shutter, disclosing the subscriber's number. When the operator inserts the plug to answer the subscriber, the heavy armature is drawn backward, and held fast in its normal position so long as the plug remains in the jack. The aluminium shutter, of course, resumes its normal position at the same time.

As before explained, the front bush of each jack is connected to this restoring circuit, and the connections of the operator's instrument are so arranged that, when she touches this bush with the tip of one of her plugs, part of the current is shunted through her receiver, showing her that the line is engaged. As one of the connections is dependent upon the contact between the inside of the bush and the sleeve of the plug, which must fit somewhat loosely, the plug is provided with what we call "umbrella" springs. The ring-off indicators are of the same pattern as those above described, but are so arranged in connection with the listening keys that when the operator's instrument is in circuit the indicator is locked, but is free to respond to the subscriber's ring-off current, when, by pushing the lever forward, this instrument is cut out of circuit.

This class of board with self-restoring indicators is being introduced into London at the same time as the subscribers' lines are being metallic-circuited, and this work will be entirely finished in a few months. One of the principal exchanges fitted with this class of board is that at Lime-street, City.

It is to be noted that, as these self-restoring indicators require permanent current to keep them locked while the lines are in use, special arrangements have to be made at each exchange for providing this current. As a typical case, I may mention that at Lime-street the current is supplied by 12 E.P.S. cells of 23 L type, charged by an Elwell-Parker dynamo running at 800 revolutions, and giving an output of 45 amperes at 15 volts. This dynamo is driven by a Tangye gas engine of 1 H.P. nominal. The engine also drives the generators which supply the ringing current. One-half of the cells—*i.e.*, 6—are in use at one time, arranged in three groups of two each; and each group supplies current for one-third of the whole exchange—*i.e.*, about 1,300 indicators. The current for the operator's transmitters is supplied by a similar number of cells divided in the same way. In this case each group supplies current for about 30 transmitters. To prevent overhearing it is found essential that the circuit of each transmitter should be taken separately by direct leads from the terminals of the batteries. A duplicate set of cells is provided, and one set is being charged whilst the other is in use.

From what has previously been said as to the number of jacks required for an exchange with 5,000 subscribers' lines, and the increased proportion in the number required when the exchange is fitted for 8,400 lines, it is evident that, apart from cost, the question is a very serious one; indeed, it becomes so serious that while on every hand it is acknowledged—and I think rightly acknowledged—that the multiple system is the best, a point may be reached where the vast number of jacks and large quantity of cables used introduce troubles almost equal to those previously overcome by the use of the multiple board. In America they are trying to meet the difficulty to some extent by the introduction of what is known as the "divided multiple" board, whilst I have endeavoured to meet it by the use of flat boards. The weak feature of the divided board is that no connection is made without being dealt with by two operators, and, consequently, the chief advantage of the multiple system—viz., that the operator who receives a call completes the connection—is lost. But with the flat board, fitted as I shall presently describe, this advantage is retained, whilst, broadly speaking, one-half only of the line jacks and cable are needed.

It is about eight years since I commenced the use of flat boards, when a small one was fitted at Paisley. The working of this board proved that the flat board as a system, if fitted with the proper material, could be worked very successfully. I am aware that flat boards had been tried in this country before that date, and that some were in use in America; but, so far as I can learn, the number of jacks used was not less than that on the ordinary upright board. I, therefore, cannot see the reason for introducing them, unless, indeed, it was considered they were better flat than upright from an operating point of view. I am aware that there are in this and in other countries telephone engineers of the highest reputation who are not at one with me on the question of the advisability of introducing flat boards; but, after the fullest and most mature consideration, and experience of their working for several years, I see no reason why they should not be used largely under certain conditions. When flat boards are fitted up in comparatively small exchanges the saving on the jacks and cable is not equivalent to the extra expense of the framework, and therefore I do not recommend their use for small exchanges. But for large exchanges, with from 2,000 to 8,000 subscribers' lines, there is to my mind no doubt that this is the best class of board to use.

The principal reasons for this opinion are—

1. That, in consequence of the smaller number of jacks and quantity of cable used, better speaking results are obtained, and fewer faults occur. I have only to point out to you, as electrical engineers, that for an 8,000-line exchange the number of soldered connections is reduced in the flat, as compared with the ordinary upright board, by over half-a-million, to bring this point of efficiency forcibly before you.

2. In many cities it is very difficult to find switch-rooms large enough to take from 5,000 to 8,000 subscribers' lines; but with the flat-board system this difficulty does not exist to the same extent, as practically they take only half the floor space required for upright boards.

There are likewise the questions of the cost of the boards, rent of switch-rooms, lighting, heating, &c., which bear some proportion to the space occupied; but these are secondary considerations, the principal one being efficiency.

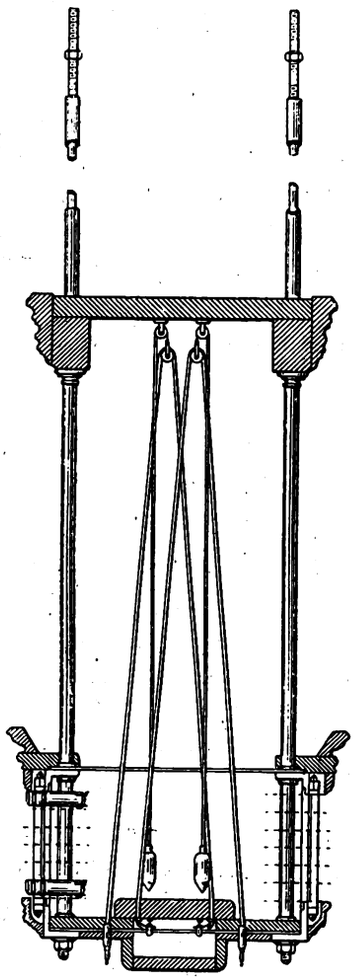
I should like to make it perfectly clear that, while I consider flat boards the right pattern to use under certain conditions, I do not recommend their use in all circumstances. With self-restoring indicators, which do not require to be within reach of the operator, and may consequently be placed overhead, and the jacks for use with which have no breaking contacts, with the consequent trouble arising from dust, I consider them the right class of board to use. I also consider the flat board the best to use in connection with exchanges of all sizes worked on the call-wire system.

Fig. 6 shows a section of the type of flat board with self-restoring indicator before referred to. It will be seen that when a plug is inserted into a jack the springs of the jack do not break any connection, and when the plug is withdrawn there is no contact point to be restored.

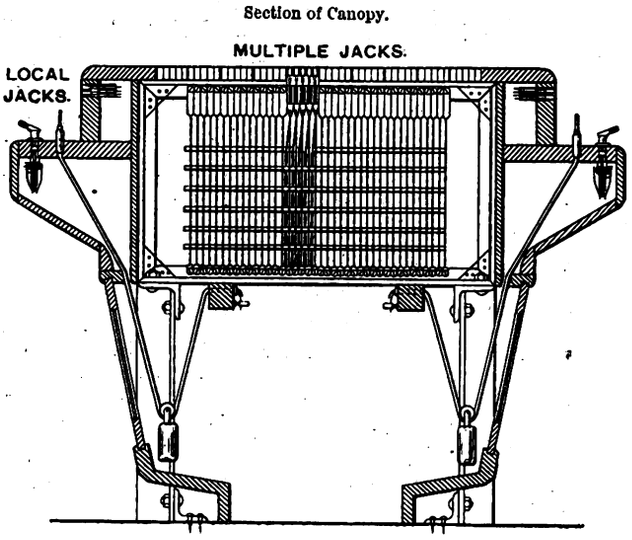
The table carries the multiple spring jacks, the barrels all facing upwards. The local, or home-section jacks, which are always used when answering subscribers, are at the side on the upright. The listening and ringing keys are fixed on a shelf at the side of the table, one half of the cords and plugs being fitted on the same

Digitized by Google

shelf, and the other half in a canopy above the table, which canopy also carries the self-restoring indicators. The lower plugs are the answering plugs, and are inserted in the local jacks only; the overhead plugs are used only for making connection with the line jacks on the top of the table. The operators (FIG. 7), each working 50 subscribers, sit on both sides of the flat table; and the 6ft. 6in. section of multiple jacks, which, on the upright board, is common to four operators with 200 subscribers, is here common to eight operators working 400 subscribers. The framework is built of T and L iron



Section of Canopy.



Section of Table.

FIG. 6.—Flat Board with Self-Restoring Indicators.

faced with wood, the details being as shown by sectional drawing at Fig. 6. Vertical oblong iron frames cross the tables at regular intervals of 11½in. for carrying the jacks and cables. The ends of the strips of spring-jacks rest on and are fastened to the upper edge of these frames, the jacks being placed in a vertical instead of a horizontal position. The cables are carried by racks inside these frames. Each block of 100 jacks occupies a space of 11½in. by 2½in., and as there are six such blocks in the length and 10 in the width of the multiple, it will be at once seen that the board has a capacity of 6,000 lines. A special type of 63-wire cable is used. The cable is formed of seven groups of three strands of three wires each, laid side by side and covered with braided cotton, the external dimensions of the cable being 1·312in. by 0·260in. The canopy is hung from the ceiling by rods at 3ft. 3in. centres, and, as before mentioned, carries the indicators and half of the connecting plugs and cords. The strips of indicators are fixed in the sides of this canopy, being hinged to allow of their opening outwards for convenience of inspection and repairing.

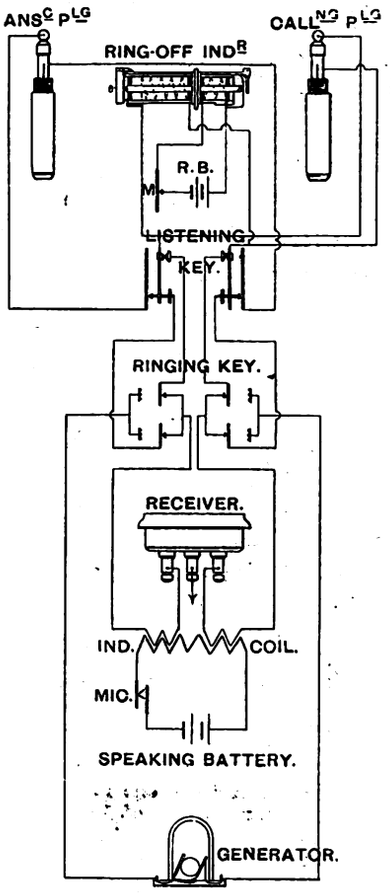


FIG. 6A.—Diagram of Branching System with Self Restoring Indicators

In connection with flat boards I mentioned the call wire, and this introduces us to a system of working telephone exchanges differing largely from any I have previously described. The use of this system has been very much discussed by telephone experts. In the call-wire system each subscriber has, in addition to his direct line to the exchange, the use, in common with a number of other subscribers, of a wire known as the "call wire," which, starting from the exchange, is branched into the offices of, say, 50 subscribers.

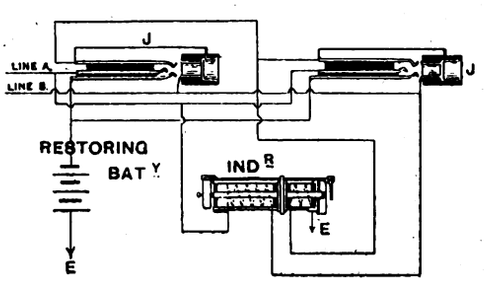

FIG. 6B.—Diagram of Branching System with Self-Restoring Indicators

On this call wire the operator attending the subscribers is continuously listening in the exchange. The subscriber's instrument is fitted with a switch which enables him to place it in connection with the call wire, on which he asks for the subscribers he requires. These, of course, are connected on his direct wire, and are rung up by him, the operator not interfering with the connections until told on the call wire to clear. It will be seen from this that when a subscriber takes a long time to answer

Digitized by Google

his bell (and there are many of them who do so, especially in London) he has to explain to the calling subscriber the reason of the delay, which would, in all probability, have been otherwise attributed to the operator. There being 50 subscribers connected to the telephone of each listening operator, it is evident that any number of them may try to speak at the same time; but here, as in all matters of business, common sense, as a rule, prevails, and a subscriber coming on to the call wire and hearing others talking to the operator does as he would do if booking a ticket at a railway office—*i.e.*, takes his proper turn—and so the calling is done without confusion, and more quickly than with the indicator system. It must be clear to everyone who considers the matter that an operator cannot attend to two subscribers at the same time; and, generally, it is quite as satisfactory to a subscriber to listen until he hears that the operator is free, as to ring time after time until the operator is able to attend to his call. It must be obvious, however, that the number of subscribers a call wire will accommodate is limited, and, as hereafter explained, great confusion would arise from overloading it.

I have before now been accused of something like inconsistency in advising in favour of this system in some places, and against it in others. In deciding upon any particular case the local circumstances have to be taken into consideration, and, after a careful study of the subject, the decision I have arrived at is that, given a town where all, or nearly all, the subscribers' lines terminate in one exchange, there is no doubt that the call wire gives the most perfect service. For this reason we have introduced the call wire into Glasgow and nearly all the towns in Scotland. We are also

Fig 7.- View of Operator, showing Breast-Plate, Microphone and Receiver.

introducing it into Manchester. It would, however, be absolutely unworkable in London. The full explanation of this would take more time than can be given to it in a Paper of this kind; but, broadly, it may be said that in a great city like London, where there are a large number of exchanges, and consequently the subscribers lines terminate at a number of different centres, the call wire becomes unsuitable. Let us take an instance. Suppose a subscriber on our King's-cross-exchange, whose office has been fitted with the call wire, wishes to communicate with a subscriber on Lime-street exchange, in the City, he presses his call-wire key and gives the listening operator the number of the subscriber he requires. The operator has then to do one of two things: she has either to cut herself off from the local call wire, in which case the main feature of the call wire, viz., continuous listening, is sacrificed; or to connect her telephone, as well as the call wire with its 50 subscribers, on to a call wire to the city. Other operators in the same exchange may have been asked by their subscribers for subscribers in the City, and may also have connected their call wires to the same City wire. In the event of a connection having to be made through two or three exchanges this trouble would be increased, and it would often be found that operating would be rendered impossible, owing to the large number of subscribers connected together all clamouring for their instructions to be taken first. The effect would be somewhat similar to that of a crowd of people attempting to rush out of a public building, on an alarm of fire, through a doorway too small to accommodate them; they simply get jammed in the doorway, with the unhappy result that they perish in the attempt. In the same way the subscriber at King's Cross might stand at his instrument and perish before he succeeded in getting through to

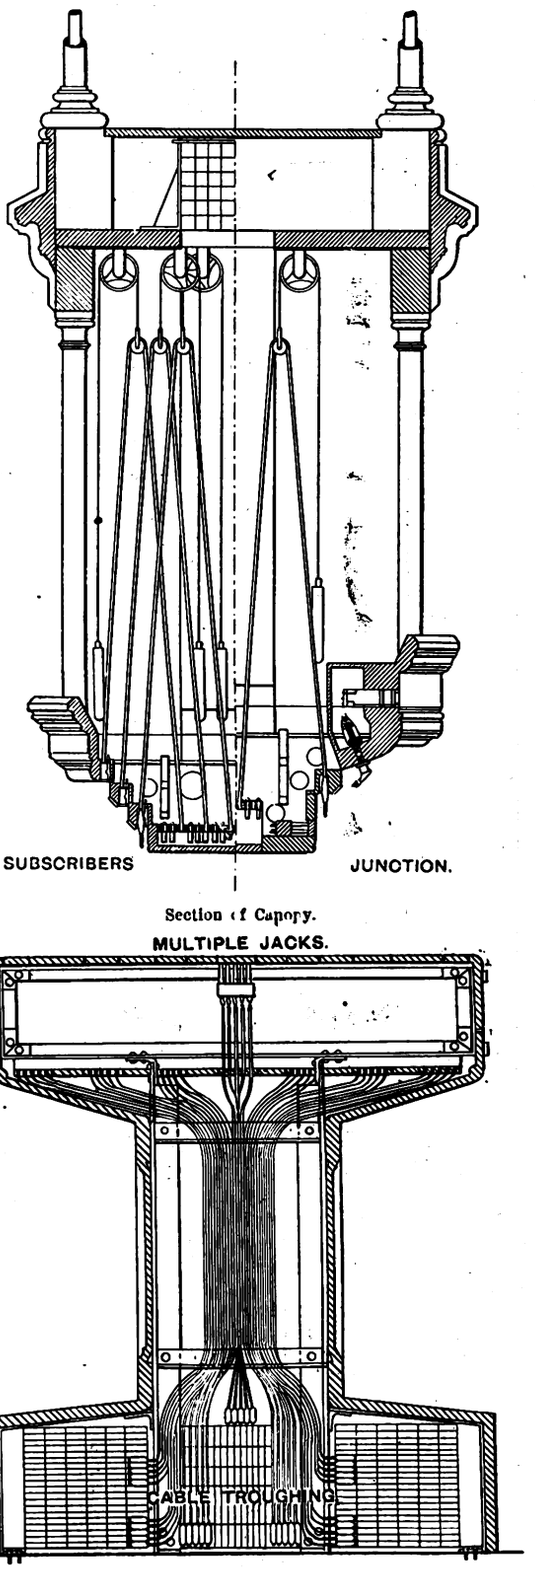

Fig. 8—Manchester Board.

the subscriber in the City. With this explanation it will, I am sure, be apparent to everyone who thoroughly studies the matter how it is that the call wire may be successful at one centre where all, or nearly all, the subscribers' lines are grouped in one exchange, and be a complete failure if introduced into an exchange system like that of London.

Digitized by Google

All things being considered, we find that the call wire gives more satisfaction than the indicator system, and it is perhaps to be regretted that it cannot be introduced under all circumstances. We had the indicator system with multiple boards at work for many years at Glasgow, and we changed to the call-wire system. Nine months after the introduction of the new system the subscribers were asked whether they preferred the call-wire or the indicator system previously in use, with the result that 95 per cent. of the subscribers were in favour of the new system; and it was this result that decided the question in favour of its introduction into Manchester.

The call wire has been in use almost since the introduction of telephone exchanges, and here again I find that our friends on the other side of the Atlantic at a very early date saw the advantages to be derived from it, with both the make-and-break and the branching system. It is the latter system which is being introduced at Manchester.

It so happens that at Manchester 90 per cent. of our subscribers have their lines terminating in the central exchange, and, consequently, it is a highly-suitable place for the introduction of the call-wire system. We are now installing it there in connection with a new exchange which is being fitted with flat boards.

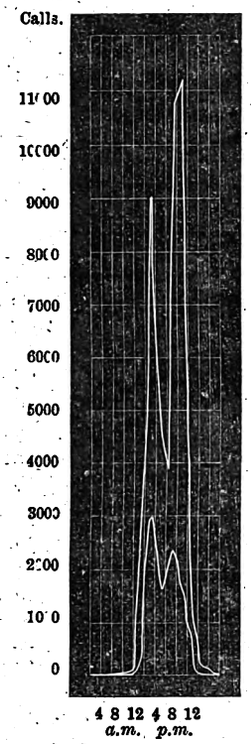

FIG. 9.—Diagram showing Originating Calls. Upper Curve: Liverpool.

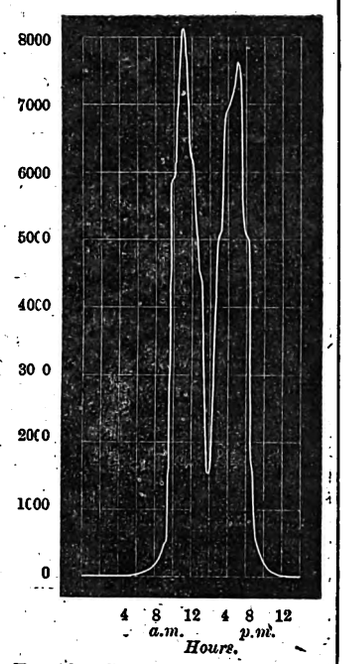

FIG. 10.—Curve showing Calls at Manchester Central Exchange for one day.

The Manchester board is illustrated in the drawing Fig. 8. It will be seen that it differs somewhat in detail from that with self-restoring indicators which has been already described. The board will accommodate 7,200 subscribers' lines, and is now being fitted complete for 4,800, with the necessary trunk and junction wires in addition. The design of the framework has been so modified as to allow the operators to get nearer to the line jacks, which gives greater facilities for operating.

I may now refer to a few load curves (FIGS. 9 and 10) I have prepared showing the number of calls passing through our busiest exchanges. At the top of these we find Liverpool, where the average number of calls per subscriber per day amounts to 18·6. The pressure of the work will, however, be better understood by noticing that at certain hours of the day the number of calls is very high. For instance, between 4 p.m. and 5 p.m. the total was 11,050. I believe this is higher than is to be found in any other exchange of equal size in this or any other country.

An important part of an exchange system in a place like London is the proper arrangement and working of the junction wires between the different exchanges. I have found that the best way to arrange these is to have, in addition to the direct wires, a central juction-wire exchange, between which and every other exchange two or more wires are provided. It will be readily understood that in a system like that of London, where there are 37 exchanges, it would be impracticable to run from each new exchange opened in the suburbs direct wires to all the others. Therefore the central junction exchange becomes a necessity. It is obvious, however, that such a central exchange must introduce extra operating, and consequent delay, into the service; and, therefore, where we have as many as 60 or 70 messages per day between any two exchanges, we provide two direct junction wires. Beyond this, an additional junction wire is provided for each 40 messages per day. Taking the average duration of each call as three minutes, it will easily be seen that, to meet the maximum pressure at the busiest time of the day, so many junction wires have to be provided that the average time each is in use amounts to only two hours out of the 24.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April 3, 1896.*

New York Academy of Sciences.—The third annual exhibition of the New York Academy of Sciences was held on the afternoon and evening of March 26th, and was attended by a large and enthusiastic gathering. This is one of the oldest scientific bodies in America. The department of electricity was the centre of greatest attraction, owing to the exhibition of Röntgen radiographs, the results showing a marked advancement in this absorbing field of investigation. In the evening Prof. Pupin, of Columbia College, gave a formal lecture on the methods of using the Crookes' tube for obtaining Röntgen effects, and after the lecture those who desired were permitted to examine their own bones with the aid of a device produced by Mr. Thomas A. Edison, which that gentleman calls a fluoroscope.

Electric Power on the Brooklyn Bridge.—Everything tends to the ultimate use of electricity as the motive power for the Brooklyn Bridge cars. On March 23rd, at the regular meeting of the trustees, Chief Engineer Martin made a report upon the results of the experiment of using electric motor cars for switching purposes. His report was very favourable, and he recommended that a power plant of larger capacity be built. The proposed plant will have an engine capacity of 2,500 H.P. and electrical generators of about 1,600-kilowatt capacity. It is proposed to do all the switching of trains by electric motors, and in case of failure of the cable, the motor cars will be capable of running four-car trains across the bridge at intervals of 60sec. Mr. Martin's report was approved, and plans for the new power house will be advertised for at once.

Consolidation of Electric Heating Interests.—Last week the consolidation of the various electric heating companies was effected in Boston, the new company absorbing these interests being known as the American Electric Heating Corporation of Boston. The capital stock of the new concern is $10,000,000, and all patents, processes and devices throughout the country that are believed to be of value will be purchased. Mr. James I. Ayer, the well-known electrical engineer and manager, is general manager of the new combination.

Franklin's Will.—The will of Benjamin Franklin was probated in Boston on March 26th as a foreign will. The will was probated in Philadelphia about a century ago, but in view of the legal disposition of the Franklin Fund in Boston, which amounts to several hundred thousand dollars, and which was created by Franklin's will, it was deemed necessary to have the document probated in Boston. The will was drawn up on July 17, 1788.

The Edison Fluoroscope.—Mr. Edison, who has been extensively experimenting with the Röntgen fluorographic screen, has finally devised a practical apparatus for its application. The instrument is intended more particularly for the use of surgeons and physicians. It is a very simply-constructed device and has been named by Mr. Edison the fluoroscope. It consists of a tube about 8in. long, larger at one end than at the other. The smaller end is so arranged as to fit closely about the forehead and eyes; the larger end is covered by a piece of cardboard, on the inner side of which is a piece of white cloth coated with tungstate of calcium crystals. A handle placed on one side enables the observer to hold the instrument. The vacuum tube is placed in a wooden box and the hand or object

Digitized by Google

to be examined is laid on top of the box, over the tube. The observer then fits the fluoroscope to his eyes, and looks down. If Röntgen rays are being emitted from the tube the tungstate crystals fluoresce, and the observer can plainly see the shadow of the object being examined. Any motion of the object is perfectly visible through this instrument.

Nikola Tesla's Investigations.—During the past week interviews with Mr. Nikola Tesla have been published in several of the New York daily newspapers, and prominent articles have been printed as coming from him under such headings as "May Signal the Stars," "We may Signal to Mars," &c. The gist of all the gush so printed is that Mr. Tesla has revived his old experiments of communicating intelligence from one part of the earth to another part without the aid of wires, using as a means therefor the principle of propagation of electric waves. "Now, why is it not equally conceivable that a disturbance on the earth's surface should produce some tangible effect on other planets?" asks Mr. Tesla.

LEGAL INTELLIGENCE.

Re The Coventry Electrical Engineering Company (Limited).

At the Coventry County Court, on Wednesday, Mr. Walter Browett applied on behalf of the Northern Electric Wire Company, of Sedburgh Mills, Halifax, electric wire and cable manufacturers, for the withdrawal of their petition for the compulsory winding-up of the Coventry Electrical Engineering Company. Counsel stated that terms had been agreed upon between the debenture-holders and the petitioning creditors. Mr. Maddocks for the debenture-holders, Mr. Wilks for the Company, and the liquidator (Mr. S. T. Peirson) consented to the application, which his Honour granted.

Walter v. Central News (Limited).

The hearing of this case (referred to in our issue of April 3rd) was resumed on Tuesday. The re-examination of Mr. Moberley Bell was continued. He had since the adjournment edited the telegrams supplied by the Central News. It was not permissible in editing telegrams to invent or add facts. He had counted the words in 24 telegrams supplied by the Central News, leaving out the dates and addresses. He had also counted the words in the telegrams as edited by himself. The original telegrams comprised 1,264 words. By liberally editing them he had added 793 words, or 63 per cent., making 2,057 words in all. These telegrams, as expanded by the Central News, contained no fewer than 7,947 words, representing an increase of 529 per cent. over the original number of words. The payment of 6d. a line was consistent with the Central News making a considerable profit. There were at least 100 daily papers. In addition to these they supplied news to American papers. With the expansions made by the Central News they might make out of each paper the whole cost of the telegrams. They received from the Central News a telegram briefly announcing the battle of Ping Yang. On the same day they received a letter from them, in which they said they had a telegram of 700 words describing the battle, and desired to know whether *The Times* would like to have it for their second edition. The telegram was accepted, and published in the paper. He had not been able to find any original telegram corresponding to those 700 words except that of 75 words. There were 17 telegrams supplied to *The Times* for which they were unable to find that any corresponding telegrams had reached the Central News.

At this point a conference between counsel took place, and it was announced that an arrangement had been come to by which a verdict was to be entered for the plaintiffs, with damages fixed at £5, with costs on the higher scale.

The Court approved this arrangement, and a verdict in these terms was accordingly given.

In reference to the above case *The Times* of yesterday contains the following: "In reference to a statement circulated by the Central News and printed by some of our contemporaries yesterday but not sent to *The Times*, it is sufficient to point out that the reports of the case published by the entire Press show that the assertion of the Agency that we accepted the readiness of the plaintiff to close the action is the direct reverse of the truth. The proposal to agree to a verdict against themselves, before our case was closed and before any evidence was offered for the defence, was made by Mr. Carson on behalf of the Central News and accepted by *The Times*."

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

TENDERS INVITED.—The Corporation of Sunderland are prepared to receive tenders for an evaporative tubular surface condenser, with air and circulating pumps. Specifications, &c., may be obtained at the office of the borough electrical engineer (Mr. C. S. Vesey Brown) at the electric supply station, Dunning-street, and tenders addressed to the Town Clerk (Mr. Fras. M. Bowey), Town Hall, must be in by 5 p.m. on Wednesday, the 29th inst. Our advertisement columns contain further particulars.

——— The Vestry of St. John, Hampstead, invite tenders for the supply, delivery and erection at the Central Station, Stoneyard, Lithos-road, Finchley-road, N.W., of a steam alternator, switchboard, steam and exhaust pipes, feed water heater, tank, and appurtenances, and these can be tendered for either as a whole or in part. The specification, &c., may be obtained after the 11th inst., at the offices of Mr. Arthur P. Johnson, Vestry Hall, Hampstead, to whom tenders must be sent not later than 4 p.m. of the 27th inst. Further particulars are given in our advertisement columns.

——— The Public Lighting Improvement Committee of St. Helier, Jersey, invite communications from persons wishing to establish a lighting station in that town for the supply of electric, gas, or other forms of light for both public and private purposes. Communications should be sent to Mr. P. Baudains, Ecr. Constable, Town Hall, St. Helier, Jersey. Some further essential particulars will be found in our advertisement columns, and other information can be obtained on application to the Town Hall.

——— Tenders are required for the provision and fixing of electric bells, telephones, fire alarms, &c., at the Brook Fever Hospital, Shooter's Hill, S.E., for the Metropolitan Asylums Board. Copies of the specification (which has been prepared by Prof. Alex. B. W. Kennedy), forms of tender, &c., can be obtained at the chief offices of the Board, Norfolk House, Norfolk-street, W.C. Tenders must be delivered at the offices by 2 p.m. on Wednesday, May 6th. Further particulars are given in our advertisement columns.

——— Tenders are invited for the purchase of about 45 tons of old copper, a large quantity of other metals, india-rubber, and other old telegraph stores, some particulars of which will be found in our advertisement columns. The necessary form of tender can be obtained of Mr. Chas. E. Stuart, Controller of Stores, General Post Office, London, E.C. Tenders must be sent in by 10 a.m. of Monday, May 4th.

——— The Electric Lighting Committee of the Coventry Corporation invite tenders for the supply and erection of (*a*) boilers and fittings, mechanical stokers and economiser, feed pump, &c.; (*b*) steam engine, alternator, oil filter, fittings, &c., steam, exhaust, feed, blow-off, and sundry pipes, valves, &c. Plans and specifications can be obtained from the consulting engineer, Mr. Robert Hammond, Ormond House, Great Trinity-lane, London, E.C., on and after the 24th inst., and tenders, addressed to the Town Clerk (Mr. Lewis Beard), St. Mary's Hall, Coventry, must be in by Tuesday, the 12th inst.

——— The Commissioners of the township of Rathmines and Rathgar, Ireland, require tenders for the electric lighting of the new Town Hall and offices, for which about 250 lights with the necessary generating plant will be required; also for an installation of telephones and electric bells. Tenders to Mr. F. P. Fawcett, Town Hall, Rathmines, by 10 a.m. of Monday next.

——— The Town Commissioners of Bray (Ireland) invite tenders for the supply of electrical stores and fittings for their generating station for twelve months. Tenders to the Town Clerk (Mr. P. Macdonnell), Bray, by Monday next.

——— The Bedford Urban Sanitary Authority invite tenders for the supply and delivery of vulcanised rubber cables. Tenders must be sent in to the Clerk, Mr. T. S. Potter, Town Hall, Bedford, by Tuesday next.

——— The Brighton Corporation require tenders for the supply and delivery of cast-iron and drawn steel bracket posts for suspending arc lamps. Tenders to the Town Clerk (Mr. F. J. Tillstone), Town Hall, Brighton, by the 20th inst.

——— Tenders are required for the erection and completion of general offices and house at Messrs. Willans and Robinson's new engineering works at Rugby. Tenders to the Secretary, Messrs. Willans and Robinson (Limited), Picton House, Thames Ditton, Surrey, by the 30th inst.

——— The Royal Company of Portuguese Railways require tenders for the supply of electric light stores. Particulars from the offices of the Company, 28, Rue de Châteaudun, Paris, and tenders, addressed to the Ingenieur Chef du Service des Magasins,

Digitized by Google

Compagnie Royale des Chemins de Fer Portugais, Santa Apolonia, Lisbon, by May 6th.

TENDERS INVITED.—Tenders are invited for an electric light installation (about 180 lights), including the supply and erection of the necessary generating plant, at Ferniehurst, Baildon (Shipley Station).

——— The French Admiralty Authorities at Brest invite tenders for the supply of three steam dynamos, required in connection with the electric lighting of the French cruiser "Gaulois."

——— The London County Council require tenders for engineers' goods and stores, tools, implements, &c. Tenders must be delivered at the County Hall, Spring Gardens, by May 5th.

TENDERS ACCEPTED.—The Sunderland Corporation have accepted the following tenders for the supply of additional plant for their electricity supply station:—

Thomas Parker (Limited)	Two continuous current dynamos and Bellis steam engines, steam pipes and switchboard connections.
Babcock and Wilcox (Limited)	Two boilers.
E. Green and Son	Fuel economiser.
H. Tonkinson	Cast-iron water tank.

——— Thirty-five tenders were received for fitting up an electric light installation at the Prince of Wales Hotel, Harrogate, including the supply of the generating plant, fixing telephones, bells, &c. The tender of the Liverpool Gas Fittings Company for the sum of £1,293 has been accepted. Mr. Walter Leake is the consulting electrical engineer.

——— The Yarmouth Town Council have accepted the tender of the General Electric Company for the supply of arc light carbons for the ensuing twelve months, at £6. 12s. per 1,000 pair, and £3. 3s. per 1,000ft.

——— The Cheltenham Town Council have accepted the tender of the Callender Company for the supply of service cable required during the remainder of the year.

——— In connection with the tenders recently invited for works required in the erection of the new electricity supply station for the Bradford Corporation, the builders', carpenters', plumbers', &c., work has been let to Bradford firms. The wood-block flooring will be executed by the Wood Block Flooring Company, of 11, Queen Victoria-street, E.C., and gates and railings will be supplied by the Coalbrookdale Company. The reservoir and tank by Messrs. A. Broxup and Sons, of Great Heorton, Bradford. The tenders for plant (batteries, surface condensing plant, cables, travelling crane, and steam and exhaust pipes) were given in our last issue.

——— The Edinburgh Town Council have accepted the tender of Messrs. Lowdon Brothers, of Dundee, for wiring the City Chambers for the electric light at £188. Eighteen tenders were received.

APPOINTMENTS VACANT.—An assistant is required for the Physical Department of the City and Guilds Central Technical College, Exhibition-road, S.W. Salary £100 per annum. Applications to Prof. Ayrton.

——— The Blackpool Corporation invite applications for the position of resident working electrical engineer to the Corporation, in succession to Mr. John Hesketh, who has been appointed electrical adviser to the Queensland Government. Further particulars are given in our advertisement columns, and applications must be sent in to the Town Clerk (Mr. T. Loftos), Town Hall, Blackpool, by the 27th inst.

BUSINESS NOTICES.—The Jackson and Sharpe Company of Wilmington, Del., U.S.A., builders of passenger and tramway cars, &c., have opened London offices at 13, St. Ermin's-mansions, Westminster, S.W.

LIQUIDATIONS.—A meeting of the principal unsecured creditors in the matter of Woodhouse and Rawson United (Limited) will be held at 33, Carey-street, London, W.C., on Tuesday, the 21st inst., at 12 o'clock, to consider what action, if any, should be taken in the interests of the unsecured creditors in connection with certain claims which counsel has advised that the liquidators can enforce against the directors and auditors, and which claims are now offered for sale by tender.

——— A meeting will be held on May 14th, at 24, Fulham-road, London, S.W., for the purpose of receiving an account of the winding-up of the Domestic Telephone Company (Limited).

——— Notice is given of the release of the liquidator (Mr. G. S. Barnes, 33, Carey-street, W.C.) in the liquidation of the Ford-Lloyd Manufacturing Company (Limited).

——— All attempts to dispose of the patent of the International Electric Subway Company (practically its only asset) have proved unavailing, and Mr. C. W. Grimwade, the liquidator, informs us that there are no assets whatever to set off against the Company's liabilities.

BANKRUPTCY.—Mr. James Nicoll, C.A., Greenock, has been appointed trustee in the bankruptcy of John H. Cox, electrical engineer, of Greenock. Claims by May 8th, and meeting of creditors at the Court House, Greenock, on May 29th, at 11:30 a.m.

PRESENTATIONS.—Mr. W. B. Edgar was presented by the electrical staff of the Crichton Royal Institution, Dumfries, with a gold chronograph on the occasion of his leaving the Institution, where he has acted as Dr. Bottomley's assistant. Mr. Edgar joins Messrs. Johnson and Phillips' staff at Charlton.

——— Mr. E. Thomas, manager of the Cork District of the National Telephone Company, was on Monday presented with a gold watch, chain and pendant by the *employés* of the Company on his promotion as local manager of the Dublin district. Mr. Thomas has been in the Company's service at Cork for five years.

PERSONAL.—Mr. W. S. Graff Baker announces that he has severed his connection with the General Traction Company (Limited), and has taken offices at 13, Austinfriars, London, E.C.

TELEGRAPH WIRE AND APPARATUS EXPORTS.—The value of the telegraph wire and apparatus exports for March amounted to £21,238, against £109,840 in the preceding month, and £19,598 and £113,423 in the corresponding months of 1895 and 1894. The figures for the quarter, however, show a considerable improvement compared with the same period of last year, the totals being £167,064 and £44,604 respectively.

EXPORTS TO SOUTH AFRICA.—Under the classification of "electrical" the value of goods exported from this country to South Africa for the week ended April 4th was £1,849, made up as follows:—Cape Town, £831; Algoa Bay, £142; East London, £242; Natal, £49; Delagoa Bay, £585.

NEW GLOW LAMP PRICE LIST.—We have received from the Sunbeam Lamp Company (Limited), of Gateshead-upon-Tyne, their latest illustrated price list of glow lamps. Among the various types we notice high-voltage lamps for pressures up to 230 volts with either single or double filaments. The list is well arranged, and gives, besides the prices for lamps and a few accessories, some views of departments in the Company's factory.

ELECTRIC LIGHT REQUISITES.—Messrs. Sunderland, of Halifax, have just issued a catalogue of electric light requisites, &c.

PRIVATE TELEPHONES.—The National Telephone Company notify that they are now prepared to erect and sell outright telephone instruments, wires, and complete installations for warehouses, offices, institutions, &c., and call attention to the low price at which instruments are now provided by the Company for these purposes. A list of many well-known establishments so fitted is given. Catalogues and estimates can be obtained on application to the Company at the District Manager's office, 58 and 59, London Wall, E.C.

AYR.—The Special Tramways Committee of the Town Council have presented a report on the question of the proposed construction of a system of tramways from Prestwick, through the town of Ayr, and on to the Burns monument. The Committee recommend the Council to proceed with the scheme, and to employ electricity as the motive power. After discussion the Council decided to remit the report to the Bills Committee.

BANGOR.—Major Philip Cardew, R.E., held a Board of Trade inquiry on Wednesday into the application of the City Council for a licence to supply electrical energy. The application was opposed by a section of the ratepayers. The applicants were represented by Mr. Marshall, while Mr. E. J. Griffith, M.P., appeared for the objectors. After evidence in favour of the scheme had been given by Councillor H. Lewis, Mr. Marshall called several influential ratepayers who were willing to take current if it were available. The first of these was the Bishop of Bangor, who said that at present he paid £20 a year for gas for the Palace and about £80 for the Cathedral. He was favourable to the scheme, and would have the electric light at the Palace at any reasonable cost, and he understood it would also be adopted at the Cathedral and the Training Colleges. By way of cross-examination, Mr. Griffith, M.P., asked "Do you know that the electric light would cause noise, smoke and vibration?" His Lordship replied: "No. I know that the manufacture of the electric light might cause noise, smoke and vibration, but not the light itself," an answer which evoked considerable laughter. Mr. E. A. Young (quarry manager for Lord Penrhyn) said he had made up his mind to put down an independent installation if he could not obtain current from the Corporation. He had Lord Penrhyn's permission to support the scheme; at present he took about 1,000,000 cubic feet of gas per annum, but the quality was very poor indeed. The Chairman of the Electric Lighting Committee (Dr. Edwards) said they had already received definite promises to take over 3,000 lights, and if the present application was not granted the Council would have to apply for a Provisional Order, and this would delay the introduction of the electric light till 1898. The present gas supply was so bad and so insufficient that the need for the electric light was urgent. Principal Reichel, of University College, and Mr. R. Davies (Chairman of the Pier and Ferry Company) also gave evidence in support of the application, while Messrs. F. H Medhurst and Fawcus gave technical details of the scheme.

Digitized by Google

Amongst the witnesses called by Mr. Griffith was Alderman T. Lewis (Chairman of the Water and Gas Committee), who was surprised to hear that the gas was bad. It was inconceivable that the proposed scheme could be anything but a failure! He thought that Bangor was one of the best lighted town, in Wales. The Gas Manager (Mr. J. Smith) and one or two other witnesses also opposed the scheme.

BELFAST.—At a recent meeting of the Electric Light Committee, the borough electrical engineer (Mr. Victor A. H. McCowen) submitted a report on the progress and development of the electricity works. After discussion it was decided to instruct Mr. McCowen to examine and report upon sites available for the erection of a generating station capable of considerable extension and of meeting the city's requirements for some time to come, in order that, should the Council decide to enlarge the producing capacity of the works, the Committee would be in a position to carry out these extensions.

BLACKBURN.—At the last meeting of the Gas Committee it was decided to increase the salary of the borough electrical engineer (Mr. A. S. Giles) by £50 per annum. It was also decided to recommend the Town Council to make application to the Local Government Board for sanction to borrow £3,000 for providing an additional steam dynamo, &c., at the generating station.

BLACKPOOL.—At the last meeting of the Town Council the minutes of the Street Lighting Committee recommended that additional gas lamps be erected in the Lytham-road. The Chairman of the Electric Lighting Committee took exception to this, and moved an amendment that electric arc lamps be substituted. After a long discussion the amendment was carried by nine votes to seven.

BOLTON.—The Gas Committee of the Town Council, at their meeting on Tuesday, considered the applications received for the appointment of borough electrical engineer, in succession to Mr. J. H. Rider. There were about 50 applications in all, and the following were elected to appear before the Committee on Wednesday next, when the final selection will be made:—Messrs. N. Applebee, Cardiff; H. W. Couzens, Taunton; E. W. Dickinson, Bolton; A. Ellis, Southport; F. Teague, Coatbridge; and J. Pilling, Bolton.——From the financial returns which have just been presented it appears that the receipts for the Electricity Department for the month of March were £1,541, against £461 in the corresponding month of 1895.——For some time past complaints have been made as to charges made for electric current. Under the present system large consumers are entitled to discounts, and it is contended that this presses unduly on the small consumer. At the last meeting of the Committee the electrical engineer (Mr. J. H. Rider) submitted a report as to the charges made in other towns, including Brighton. In order to furnish a practical example of the effect of the Brighton scale, the electrical engineer was authorised to arrange for a demand indicator being placed in one of each of the following description of premises, viz., private dwelling house, shop, mill and works. It was also reported that there were 117 customers connected to the mains, with an equivalent of 9,525 8-c.p. lamps. A continuous supply of current is now available.

BRADFORD.—A Local Government Board inquiry will be held at Bradford on Tuesday next in connection with the application of the Town Council to borrow £40,000 for electric light extension purposes.

BRANDON.—The District Council are at present considering a proposal from Messrs. Straker and Love to supply electric current for lighting the greater part of the district by means of 16 c.p. incandescents at 33s. per lamp per annum, the Council to find and erect poles, wires, lamps, &c.

BRIGHTON.—In the abstract of Mr. Wright's report in our last issue, we gave some figures showing the increase in the demand for electric current in this town. We, however, omitted to state that the figures represented the number of units sold in the first two months of the years 1894, 1895 and 1896 respectively.

CHELTENHAM.—Mr. Kilgour's report to the Town Council states that there is now an equivalent of 6,150 8 c.p. lamps connected, while about 700 wait connection.

CHURCH LIGHTING.—It has been decided to wire the Duncansburgh (Inverness-shire) Established Church for the electric light.

COMMISSION OF SEWERS (LONDON).—At the last meeting of the Commissioners an application from the National Telephone Company for permission to lay telephone wires under certain thoroughfares was referred to the Streets Committee for consideration and report.

DARWEN.—A Committee has been appointed to consider and report upon the advisability of the Council applying for a Provisional Electric Lighting Order.

DOCK LIGHTING.—The Graving Dock Committee of the Tees Conservancy Commissioners are considering the question of lighting the dock electrically.

DUDLEY.—The Town Council appear to be dissatisfied with the manner in which the streets are at present lighted, and a committee has been appointed to consider and report upon the matter. Electric light has a good chance here.

DUNDRUM.—Mr. W. B. Barrington recently held an inquiry at Dundrum on behalf of the Board of Works, Dublin, into the application of the Rathmines, Dundrum and Blackrock Tramways Company for powers to construct a tramway on the overhead trolley system between Rathmines and Dundrum. Mr. Barrington said the inquiry only concerned the undertaking from an engineering point of view. Mr. Drury, on behalf of the Rathmines Commissioners, raised an objection to the jurisdiction of the inquiry, and contended that the plans, &c. submitted by the promoters' engineer (Mr. Fuller) should be altered so as to meet the views of the Commissioners. The Company acquiesced in this view and the inquiry terminated.

EDINBURGH.—At the fortnightly meeting of the Town Council on Wednesday Mr. Treasurer M'Crae submitted the draft provisional estimates of expenditure for the next financial year. He stated that the accounts of the Electric Lighting Committee were extremely satisfactory. Whereas last year they expended an excess of income of £1,260, this year it was estimated that a surplus would result of £7,490. This was after giving effect to the contribution from the Lighting Committee at the reduced rate of £18 per lamp, showing an actual increase of £8,750 over last year's figures. A proposal to construct a circular tramway at or near the proposed extended boundary of the City was afterwards discussed, and it was remitted to the Lord Provost's Committee to consider whether this should be worked by electric or other motive power. The Electric Lighting Committee are considering the charges to be made for electrical energy as from May 1st next.

EXETER.—At the meeting of the City Council on Wednesday last the special Electric Lighting Committee reported that the Local Government Board had sanctioned the transfer of the undertaking of the Exeter Electric Light Company, and had also sanctioned the Council's application to borrow £7,500 to complete the purchase, the loan to be for a period of 15 years.

GREAT YARMOUTH.—The municipal electric light works continue to progress in a satisfactory manner. From the report of the surveyor for the month of March, it appears that the income for the month was £180. 16s. 8d. and the expenses £142. 8s. 11d., leaving a balance of £38. 7s. 9d. towards interest, sinking fund, charges, &c., which altogether amount to about £100 per month.

HAMPSTEAD (LONDON).—The Vestry have decided to lay an electric light main from Alexandra-road to High-road, Kilburn, for the purpose of supplying current to private consumers in Belsize-road, at an estimated cost of £462.

HARROGATE.—The Town Council have received the formal sanction of the Local Government Board to borrow £25,000 for electric lighting purposes.

HOSPITAL LIGHTING.—At the recent annual general meeting of the Governors of the Norfolk and Norwich Asylum, the quarterly report stated that the subject of the lighting of the hospital, which was unsatisfactory and expensive, had been under consideration for nearly two years. Experiments had been made in one of the wards with the incandescent gaslight, but the Committee who had charge of the matter reported that, although an improvement in brilliancy upon ordinary gas, the system was not suitable for use in the hospital. Inquiries as to the cost of the installation of the electric light were then made, with the result that the estimated capital expenditure was put at £800. The Board, therefore, in view of the superior healthiness, cleanliness and convenience of the electric light, advised that the hospital be wired and fitted up for the electric light, and that an arrangement be come to with the Norwich Electricity Company for supplying current. Mr. J. Holmes said, as to the relative cost of the electric light and gas, with care and economy the cost of the former would be only about £275 a year, whereas the present cost of the gas used for lighting purposes alone was about £300. Sir Peter Eade strongly supported the introduction of the electric light, stating that a hospital required a light that could be localised by means of more or less portable lamps, and from this point, and as to purity and cleanliness, no artificial light could be better suited to the purpose than that of electricity. The Rev. Dr. Barrett stated that a member of a large firm in Norwich had informed him that three years ago he adopted the electric light in his factory. In connection with the firm there was a benefit fund, and during the few years preceding the adoption of electricity benefit was received every year on account of sickness by 11 per cent. of the workpeople, but since the introduction of the electric light the number receiving benefits were only 4 per cent. The recommendations of the report were then agreed to.

ISLINGTON (LONDON).—Although the electricity supply station at Eden-grove, Holloway, was only opened in March last, the Electric Lighting Committee have already, we understand, under considera-

Digitized by Google

tion the urgent necessity of an increase in their plant, it being proposed to extend the system from Seven Sisters-road to Highgate-hill, a long stretch of thoroughfare composed of a fairly even mixture of shop and residential premises. The Northern Polytechnic is also to be fitted up for the electric light, and current will be required, as previously noted in these columns, for the lighting of the Agricultural Hall. The Committee have, in fact, already decided to expend about £2,000 in electricity meters and converters.

LEEDS.—At the meeting of the Highways Committee on Wednesday the minutes of the Tramways Sub-Committee recommended that Dr. J. Hopkinson be appointed engineer to supervise the construction of the proposed electric tramway from Roundhay to Kirkstall, terms satisfactory to the Committee having been arranged. The recommendation was agreed to, and Dr. Hopkinson has been instructed to prepare the necessary plans and specifications, and the City Engineer (Mr. Hewson) is preparing plans for the power station.

MERCHANDISE MARKS ACTS.—A general order has been issued by Her Majesty's Customs in reference to discretionary powers granted to Customs officers in regard to certain matters concerning the marking of, and packages for, imported goods. The matter has interest for importers of light goods.

MONMOUTH.—The Local Government Board has sanctioned the application of the Town Council for borrowing £8,115 for electric lighting purposes.

NEWMARKET.—In view of the opposition of the District Council, the Newmarket Electric Lighting Company have decided not to proceed with their application for a Provisional Electric Lighting Order for the district.

PAISLEY.—At the monthly meeting of the Police Commission on Tuesday last, it was decided to proceed with the scheme for establishing electricity supply works in the town. A communication was received from the consulting electrical engineer (Dr. J. T. Bottomley) stating that the cost of the proposed installation would be about £25,750.

PORTISHEAD (SOMERSETSHIRE).—The District Council have decided to instruct their surveyor to make inquiries as to the cost of lighting the district electrically.

PORTRUSH.—The Town Commissioners have decided to sanction the proposal of the Giant's Causeway, Portrush and Bush Valley Railway Company to alter their system of traction from the third rail to the overhead trolley.

SWANSEA.—The Electrical Committee of the Town Council have discussed the offer recently made by Mr. J. C. Howell to take over the Swansea Provisional Order, and have decided to retain their powers for the present.

TAUNTON.—At the meeting of the Town Council on Tuesday last, the Electric Lighting Committee's report recommended that application be made to the Local Government Board for sanction to borrow a further sum of £3,000 for electric light extension purposes. In moving the adoption of the report, Alderman Potter said the balance sheet of the department showed that the expenditure during the year amounted to £3,004. 13s. 3d. and the income to £3,580. 11s. 11d., a profit of £575. 18s. 8d., or more than sufficient to pay a dividend of 3 per cent. if the undertaking were in the hands of a company. Interest amounting to £497 and the balance (£78) had been carried to the sinking fund account, leaving a net deficiency of £350 from the rates. As compared with the previous year they were in a far better position, considerable progress having been made during the year. The report was adopted.

TRAIN LIGHTING.—The North British Railway Company is conducting experiments as to the practicability of lighting their trains electrically. The Company has selected one of the Edinburgh and Glasgow trains for the experiment.

"THE GREAT TRAMWAYS SCHEME."—The *Pall Mall Gazette* on Monday last contained some particulars concerning the scheme for amalgamating into one huge undertaking the tramway service of the metropolis, to which reference was made in our last issue. Our contemporary appears to be much impressed with the particulars it has obtained of this colossal scheme, which, however desirable, must need much more than the consent of the London County Council for its successful execution.

WALSALL.—At the last meeting of the Town Council the Electric Lighting Committee's minutes stated that on March 31st there were 53 customers connected to the Corporation mains, and recommended the Council to carry out various extensions at a cost of £621. 10s. On the motion for the approval of the minutes an unsuccessful attempt was made to get the Council's sanction to the laying of mains in the greater portion of Digbeth. The Committee's recommendation was approved.

WELLS.—The City Council have received a letter from the Local Government Board relative to the proposed purchase of the gas works. It has already been decided to establish electricity supply works in the town, but the matter will be further considered at the next meeting of the Council.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

March 30, 1896.

6,890. S. BERDITSCHEWSKY, called APOSTOLOFF. London. System of distribution of electrical currents.

6,925. H. BIERMANN. London. Electric water-gauge.*

March 31, 1896.

6,943. W. J. FRYER. London. An automatic electric light door switch.

6,953. J. D. BELL. Glasgow. Improvements in controlling gear for electrically-propelled carriages or trucks.

6,980. J. ENTWISLE. Manchester. An improved electric boat-propeller. (S. N. Smith and E. S. Baring-Gould, United States.)*

6,981. J. ENTWISLE. Manchester. Improvements in electric batteries. (S. N. Smith and E. S. Baring-Gould, United States.)*

6,993. R. HACKING. London. An improved coin-freed electric meter.

7,000. L. EPSTEIN and F. MARZA. London. A process and apparatus for decomposing sodium or potassium chloride and generating electricity.

7,005. H. H. LAKE. London. Improvements in electric hammers and the like. (A. S. Barnes and P. S. Skinner, United States.)*

7,013. J. DEVONSHIRE. London. Improvements in electric meters. (C. P. Steinmetz, United States.)*

7,038. H. BÄURLIN. London. Improvements in regulators for electric arc lamps.*

7,054. L. C. WERNER. London. Improvements in electrical signal systems for railways.*

April 1, 1896.

7,074. A. J. BEAUMONT. York. An arc lamp for high voltages.

7,121. A. F. DAVIES. London. A new method of making shades for gas, electric or other lights.

1,151. F. H. NALDER, C. W. S. CRAWLEY and A. SOAMES. London. Improvements in differential automatic switches.

7,161. F. A. CHAPMAN. London. Improvements in or relating to electric light fittings.*

7,162. A. J. BOULT. London. Improvements in or relating to secondary batteries. (J. Julien, Belgium.)

7,166. M. A. SHANAHAN. London. Improvements in electric fire alarms.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1895.

5,205. LUCKOW. Secondary battery plates.

8,453. BROCKIE. Electric switches.

9,380. LLOYD and BRANSTON. Electric-firing pistols for gun mountings.

9,442. HARDINGHAM (Felten and Guilleaume). Insulating electric conductors.

9,636. SIEMENS BROS. AND CO. (LIMITED) and BOOKER. Arc lamps.

10,277. SIEMENS BROS. AND CO. (LIMITED) and LAUCKERT. Measuring electric currents.

11,544. BULLERS (LIMITED) and CHAMBERS. Telegraph poles, &c.

21,460. MORGAN. Electric motors.

24,711. DEVONSHIRE (Potter). Electric brakes.

COMPANIES' MEETINGS AND REPORTS.

Chelsea Electricity Supply Company (Limited).

An extraordinary general meeting of the members of this Company was held at the offices, Cadogan-gardens, on Wednesday, Mr. J. Irving Courtenay in the chair, to consider a resolution for increasing the capital of the Company by the creation of 20,000 Ordinary shares of £5 each, the provisions of Article IV. of the Articles of Association of the Company not to apply to the new shares.

The SECRETARY (Mr. S. J. Cluer) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, the object of the meeting to-day is, as set forth in the notice, to obtain the necessary powers for the increase of the nominal capital of the Company, as all the share capital originally authorised has been issued and fully subscribed. At the general meeting on March 4th last, I laid before you fully the position of the Company, and I need not therefore detain you now at the same length, but I shall again call attention to some of the salient points. It is evident that with the growing demand for current in excess of the present capacity of the plant the capital outlay must

Digitized by Google

increase, but the experience gained enables the outlay to be made to the best advantage and in the most economical manner. The total number of lamps added this year up to the end of March is 4,573, as against 1,098 last year, or more than four times as many in the first three months. Formal application has been made to the Board of Trade under our Provisional Order for the whole of the remaining portion of the parish of Chelsea, and as it is unopposed we expect that the application will go through in due course. This comprises the extensive district running from Battersea Bridge, along Beaufort-street, and by the Fulham-road to the Western boundary of the parish. The rapid increase in the demand for current in the present area, and this large addition to the district supplied by the Company, necessitate the immediate building of a new generating station, which will be erected on our own freehold property, and adjacent to the existing station in Manor-street, and also substations for the distribution of the current. The site selected for the new generating station has space for plant having capacity for running some 50,000 8-c.p. lamps at one time, but it is only intended to erect and equip works in accordance with the demand as it arises, though the complete arrangement has been designed. The works and plant it is proposed at once to erect and equip will furnish current to about 25,000 8 c.p. lamps fixed, and then there will be the mains and street work, which latter will be laid down with a view to carrying a larger demand as it arises. I desire to call your attention to the fact that the works costs have considerably decreased as the number of units sold have increased. During the last two years there has been a reduction in works costs of 26 per cent., and an increase in the demand for current during the same period of 43 per cent., which agrees with the experience of other metropolitan companies. Upon the general situation I may point out that we have during the past few years been adding to our renewals fund; we have cleared our accounts of some heavy items which might legitimately have been spread over several years in a suspense account, and we have this year created the nucleus of a reserve fund, to which we intend from time to time to make substantial additions. The foregoing remarks are confirmed by the fact that since 1890 the revenue of the Company has about trebled itself, for in 1890 it was £6,080, and in 1895 it amounted to £17,165, while the amount available for interest and dividends (which in 1890 was £597), was, as shown in the accounts to December 31st, 1895, £9,595. The figures for the intermediate period also indicate how the increase of the gross revenue each year has been accompanied by a large increase in the proportion which the net revenue bears to the gross. I trust I have said enough to convince you of the healthy growth of the Company, and to show you that we may expect these conditions to continue in the future. He concluded by moving the resolution.

Mr. EMILE GARCKE seconded the motion.

A brief discussion followed, in which Major R. M. Mackenzie, Mr. A. Andrew, Mr. Thomas Webb and Mr. John Hughes took part.

The CHAIRMAN, in reply, stated that the Directors intended to give the shareholders a preference in the allotment of the new shares over the applications sent in by the public. It would be advantageous to increase the constituency, however, and they could not issue a prospectus to the public, and then confine the allotment of the shares to the shareholders. The Directors had not yet decided how much of the new capital they would require to call up at once, but they would soon come to a decision. He quite agreed with Major Mackenzie as to the advantages of a reserve fund, which the Directors would be most anxious to see increased to a substantial amount. They had not yet decided as to the premium they would ask for the new shares. There was a ready market, he believed, for the Preference shares though not officially quoted; and he was informed that they had changed hands at £7. 10s. to £7. 15s.; that was for the £5 shares. The Stock Exchange had not granted a quotation to the Preference shares as the amount was so small. Until they had issued £50,000 of Ordinary shares, the latter were not given an official quotation.

The motion was carried unanimously.

A vote of thanks to the Chairman and Directors brought the meeting to a close.

County of London and Brush Provincial Electric Lighting Company (Limited).

The second ordinary general meeting of this Company was held at Winchester House, London, E.C., on Monday last, under the presidency of the Right Hon. Lord Rathmore, LL.D.

The SECRETARY (Mr. H. B. Renwick) read the notice convening the meeting.

The CHAIRMAN, in moving the adoption of the Directors' report and accounts, said: We have every reason to feel satisfied with the present position of the Company and increased confidence in its future. During the period with which the present report deals we have met with some difficulty and have had to submit to some disappointment and delays, such as are, I suppose, almost inevitable in the earlier stages of such an undertaking as ours is; but already we have, I think, a considerable measure of success to present to you. I am myself never inclined on such an occasion as the present to take too glowing or rosy a view of the situation; but still I think that, speaking in all seriousness and moderation, we may well congratulate ourselves on this—that, although we have been less than two years in existence, we stand to-day on solid ground, that we have established a large and important business, and that we have good reason to anticipate that ere long this Company, in which we have invested our money, will prove a very profitable and lucrative undertaking. Our position, in a word, is this—that the net revenue for the year 1895 has proved to be sufficient to pay in full the dividends upon our Preference capital, and to carry forward a substantial balance to the accounts of the present year, and this revenue has been earned under circumstances of some difficulty, which, although of a temporary and accidental kind, were still such as to give us a good deal of trouble, as I shall presently explain to you. Before I do so, however, I think I had better refer for a moment to one or two items in the statement of accounts as to which you would, perhaps, like some further information. You will find in the balance sheet, under the head of "liabilities," the item of "loans against security." That refers to advances which we have received from our bankers in anticipation of calls upon our Preference issue, and also against the security of certain investments which the Company had made in quoted stocks. Those investments were steadily rising in value, and we thought it was better to postpone selling them until we had received the dividends which were accruing on them. Those investments have since been sold at a considerable profit, which will go into the accounts of the present year, and in order to give honour where honour is due, I think it is right to say that for the success of that operation we are much indebted to your Deputy-Chairman, Mr. Braithwaite. The next item you will see is "sundry creditors," amounting to £12,260, and I may tell you that that sum has already been almost all paid off. Turning to the assets side of the balance-sheet you will see that expenditures are appropriated, £75,911 to the St. Luke's and Clerkenwell Orders, and £40,358 to the Wandsworth Order, the particulars of which you will find in the capital account numbers 4 and 6. As to the circumstances of these undertakings, I shall have a word or two to say presently. Then there is an item of "sundry debtors." That represents mainly debts due, or rather which were due, on management account from sub-companies and for interest on moneys advanced. Practically, all these debts have been received since the beginning of the present year. I will now deal with the working of the Company in our London districts; and first, as to St. Luke's and Clerkenwell, there we have had to confront some difficulties which we had no reason to anticipate when I last had the honour of addressing you. In the first place, objections were taken by the London County Council to the frontage of our St. Luke's buildings. Then we were met by a strike of our contractors' workmen, which lasted a considerable time, and for the time seriously interfered with our business. Then there were difficulties as to our street boxes. I am glad, however, to say that all these obstacles have now been overcome. The whole of the street work has been completed, and connections have been made with our consumers' premises; and by a temporary arrangement for the supply of current we have been able to earn a small profit upon the year. All the cables have now been drawn in. The remainder of the connections with our consumers are being pressed forward as fast as possible, and I may tell you that the amount of current supplied during the first quarter of this year has almost equalled the whole amount supplied during last year, and that it is estimated that at least five times the amount of current will be supplied in St. Luke's and Clerkenwell during the present year as was supplied in the year 1895. Meantime our station buildings, the strike being over, are proceeding, and we trust that we shall have this station completed and supplied with excellent machinery in readiness for the winter lighting. We believe that in this station we shall have one of the best in the metropolis, and we have no doubt that in the cost of running, it will compare very favourably with any other station of similar size. At Wandsworth, too, we had the disadvantage of having to deal with difficulties which were raised by the local authorities in reference to street work, and that involved us in litigation which was rather lengthy, as all the questions raised had to be thrashed out before the Board of Trade and also in the High Courts of Justice. However, we cannot blame ourselves in any way for this, because every question raised was ultimately decided in our favour, and the street work at Wandsworth is now approaching completion on the plans and according to the system we originally proposed. As anyone who travels on the South Western Railway may have observed, our station buildings are also advancing, and we have almost finished what I think will be a handsome generating station at a spot where the river Wandle joins the Thames. We may, therefore, expect that when the winter lighting begins in the present year we shall have in the metropolis two large generating stations—one on the north side and one on the south side. I refer, of course, to St. Luke's and Clerkenwell and Wandsworth respectively, two stations built and equipped with every modern improvement, having a combined power of supplying some 90,000 lamps, and the power of each of them capable of being easily doubled simply by laying down in the existing buildings additional plant and making additional connections for supplying new customers. Under these circumstances I think that, in spite of all the difficulties and delays we have been subjected to, which, as I have explained, were entirely beyond our control, and for which we were not in any way responsible, we may well congratulate ourselves on the satisfactory position in which our ventures for lighting St. Luke's and Clerkenwell on the one side, and Wandsworth on the other side, at present stands. I may add, while on the subject of our London stations, that the Provisional Order for St. Olave's has since this report was published been confirmed by Parliament, and has received the Royal Assent. As you are aware, the Camberwell Vestry has given its assent, and we are in hopes of being able to secure some additional districts in that neighbourhood which could all be easily and economically lighted from one generating station.

So much for our stations in the metropolis. I will now turn to our stations in the provinces. First, as to Bournemouth, the work of our business there has been to some extent interfered with by the change of the machinery from old to new and the rebuilding of the station, which has entailed upon us rather a heavier cost for running expenses than we had anticipated. But, nevertheless, the gross revenue at Bournemouth increased during 1895 by about £600, and the working expenses were a trifle less. I think we may confidently expect that with the rearrangement of the plant which is now being made, and also on account of some improvements which we have been able to introduce into the manage-

Digitized by Google

ment at Bournemouth, the cost of production will be still further reduced in the present year, and that the net revenue will be increased. I may mention also that the cost of production was during 1895 three farthings per unit less than it was in the year 1894, and that the amount of current supplied during the first quarter of the present year exceeded by nearly 16 per cent. the amount supplied in the corresponding period of 1895. With regard to Dover, you know that for some time our large and commodious generating station there has been completed, and we have been able since last April to give an uninterrupted supply of current to our consumers. Up to the present time the number of connections that we have is about 4,800 8-c.p. lamps; and Mr. Lawson thinks that that number will probably be doubled by the end of the year. As to Windermere, this time last year I told you we had at that time received the consent of nearly all the local authorities—seven out of nine, I think—to the granting of our Provisional Order. I am sorry to say that the other two local authorities still withhold their consent and, therefore, we have not been able to make progress at Windermere. Then there remains our station at Richmond in Surrey. You may remember that at our last annual meeting I told you that we had just then acquired the controlling influence in the Richmond (Surrey) Electric Light and Power Company, Limited, and I encouraged you to expect favourable results from that investment. I am glad to be able to tell you now that it has come out better than we expected, and we seem to have already well turned the corner at Richmond, for instead of a loss of nearly £1,000, sustained in the year 1894, a certain profit was made during 1895, and sundry charges, the liability for which had been incurred in 1894 and 1895, have been paid for out of revenue. Up to the time at which I am speaking the number of lamps applied for at Richmond is equivalent to 5,913, and 5,800 are connected with the Company's mains; and the units sold in the quarter just ended exceed the number sold in the corresponding period of 1895 by about 19 per cent., while our expenses are considerably lower. A number of lengths of mains were laid down during the year 1895, and some more extensions are now being pushed into other streets to meet the wants of consumers. I think I may encourage you again confidently to expect that before long this Richmond station will provide us with a satisfactory and handsome profit. I do not think that there is anything else in the history of our stations, either in London or the provinces, for me to call your attention to. In October last our manager, Mr. Lawson, was unfortunately stricken down by illness, but Mr. Garcke very kindly stepped into the gap and gave us the valuable aid of his experience. I am pleased to say that Mr. Lawson is now again with us, restored to health, and we now enjoy the advantage of Mr. Garcke's advice and assistance as a member of the Board, to take the place of Mr. Denny, whose resignation the directors have had reluctantly to accept. As stated in my opening remarks, I think we may look with considerable satisfaction at the last year's work, and may look forward with increased confidence to the continued success of the Company. Of course, in our earlier stages heavy expenditure has had to be incurred with only a small resulting revenue. This, however, is only a question of time, and makes our ultimate success the more certain. We shall, without doubt, be able promptly to meet all dividend payments on account of the Preference capital, both present and future, and confidently hope that before long the Ordinary shareholders will also reap their reward. I now beg to move the adoption of the report and accounts.

The DEPUTY-CHAIRMAN (Mr. J. B. Braithwaite, jun.): I have pleasure in seconding the motion, and it will be unnecessary for me to add to the clear and lucid statement of our Chairman. With regard to revenue, our experience is similar to that of the successful City of London Electric Lighting Company, with which I was associated in its early stages. We are fortunate in being able to pay the Preference dividend and to carry forward a substantial sum before either of our London stations are at work. Our provincial stations are doing well, and the outlook from all points of view is extremely satisfactory.

Mr. E. K. SMART referred to an item in the accounts for preliminary expenses.

Mr. CASH desired some information on the subject of Directors' remuneration, salaries and wages, &c.

In reply, the CHAIRMAN said that with regard to the preliminary expenses doubtless the item of £4,000 standing in the accounts might seem large, but the shareholders must remember that the expenses inevitably connected with the issue of capital were necessarily heavy. Their capital issues had been a great success, being subscribed for many times over, and the shares now stood at a considerable premium. With regard to Mr. Cash's question, the charges to which he alluded were always appropriated in proportion between capital and revenue during the period of construction.

The motion was then carried unanimously.

Mr. J. B. Braithwaite, jun., and Mr. A. H. Sanderson, the retiring Directors, were then re-elected, the payment of the interim dividend on the Six per Cent. Preference Shares agreed to, and Mr. R. H. Marsh re-elected auditor.

A cordial vote of thanks to the Chairman and Directors, proposed by Mr. Smart and seconded by Mr. Payne, was carried unanimously, and the proceedings terminated.

Norwich Electricity Company (Limited).

The annual general meeting of the shareholders of this Company was held on Wednesday at the offices, Queen-street, Norwich, Mr. F. W. Harmer presiding. The Directors' report stated that the demand for current, both for lighting and motive power purposes, has continued to increase in a most satisfactory manner, the number of customers showing a considerable increase as compared with 1894. During the year upwards of two miles of new mains have been laid, a new engine and dynamo of 200 H.P. have been added to the generating plant and a new battery sub-station erected. In order to obtain a day load for their machinery the Directors have reduced the price of current for motors run continuously during the day to 3d. per unit for all hours. The Directors anticipate that this will result in an increased and profitable revenue from boot and shoe manufacturers and others requiring motive power. £19,500 Four per Cent. Debentures have been issued during the year for the purpose of paying off the loan from Messrs. Gurney and Co., and to provide for the increased outlay for machinery, &c. The revenue account shows a credit balance of £2847. 3s. 1d., to which must be added £112. 5s. 8d. brought forward from last year, making a total of £2,959. 8s. 9d. From this must be deducted £749. 3s. 5d. for interest on debentures, &c., leaving a balance of £2,210. 5s. 4d. The Directors propose to pay a dividend of 3½ per cent., which will absorb £991. 12s. 10d., to place £1,100 to depreciation account, and to carry forward the balance.

In moving the adoption of the report and accounts, the CHAIRMAN said the income had increased from £3,786 in 1894, to £5,845 in 1895. Their anxiety was not to get fresh customers, but to be able to get machinery to supply them. At present the manufacturers were exceedingly busy; but they hoped to have the additional plant ready to meet next winter's demand. They were gradually extending their mains in all directions, and they had other projects in hand which would, no doubt, be profitable, and give them abundant work for the next year. Referring to the financial position, the Chairman said that at the time of the last meeting they were £15,000 in debt, with over £10,000 expenditure in prospect, but the Directors had such confidence in the future of the Company that instead of borrowing money at the rate they would have had to pay they obtained it on their own responsibility without applying to the public to take up shares until they felt they could show the enterprise was going to prove a financial success. As to the establishment of a sub-station on the Newmarket Road, that was constructed principally in view of the proposal to introduce the electric light at the Hospital, which had just been decided upon by the Board of Management. Repeated applications for current had been made by people in the suburbs, and in time they would be able to supply the demand; but he considered it was better to occupy themselves with the nearer territory, which was more profitable. In the Market Place and London-street there were few shops which contained the old-fashioned system of lighting by gas; in fact, they had practically driven gas out of the principal streets of the city. At the end of 1894 they had 297 customers, and an equivalent of 6,800 8 c.p. lamps were connected; at the end of 1895 they had 450 customers and an equivalent of 9,880 lamps.

The report and accounts were then passed, and a dividend at the rate of 3½ per cent. declared.

Richmond (Surrey) Electric Light and Power Company (Limited).

At a private meeting of this Company held yesterday (Thursday) at the offices, Moorgate-court, Moorgate-place, E.C., the following report of the Directors was presented:—

During the year a further sum of £2,906. 13s. 7d. has been expended on capital account for mains and meters, and for electrical instruments in the station, the necessary funds having been obtained by loan from the County of London and Brush Provincial Electric Lighting Company (Limited). The revenue account for the year to December 31st shows a profit of £230. 7s. 1d., as against a loss of £978. 19s. 8d. in 1894, while legal charges in connection with the adjustment of contractors' claims, amounting to £131. 16s. 2d., liability for the greater part of which had been incurred in the previous year, have been paid out of revenue. The total number of lamps connected was equivalent to 5,486 8 c.p., an increase of 1,746 since 1894, and a considerable additional number have since been applied for and connected in the enlarged area of supply in which mains were laid towards the end of the year. The Richmond Corporation have consented to the Company's application for power to still further increase the area of supply, and mains will be laid during the current year in several of the better residential streets. The generating plant is in excellent working order, and as the capacity thereof is sufficient to meet a greatly increased demand, no further expenditure for plant will be required this year.

Indo-European Telegraph Company (Limited).

The Directors' report for the year 1895, which will be submitted to the meeting to be held at Winchester House, London, E.C., on the 29th inst., at 12:30 o'clock, states that the revenue for 1895 amounted to £123,734 1s. 7d., compared with £119,117. 18s. 3d. for 1894. The expenses were £67,820. 10s. 4d., against £64,838. 13s. 1d. for 1894. Deducting the expenses, taking credit for £5,789. 2s. brought forward and debiting income tax, there remains the sum of £59,371. 17s. 11d., of which £10,000 has been placed to reserve, and £10,625 has been paid as interim dividend, leaving a balance of £38,746. 17s. 11d. The Directors now propose a dividend for the six months to December 31st of 17s. 6d. per share, making, with the interim dividend, 6 per cent, and a bonus of 2?s. per share, both free of income tax, making 10 per cent. for the year, £6,871. 17s. 11d. being carried forward.

Messrs. L. Delbrück and C. W. Earle offer themselves for re-election as Directors.

The dividend and bonus will be payable from May 1st. The transfer books are closed from the 15th to the 29th inst.

Oriental Telephone and Electric Company (Limited).

The report of the Directors of this Company for the year ended December 31st last, to be presented at the general meeting at Cannon-street Hotel, London, on Wednesday next at 1 o'clock, states:—

That the revenue account for the year shows a balance to credit of £8,675. 2s., which has been transferred to profit and loss. Including the sum of £706. 5s. 3d. brought forward, there is an amount of £9,381. 7s. 3d. available for disposal. The Company's license from the Government of Ceylon expired on December 31st, the Government refusing to extend it, having resolved to work the telephones through their telegraph department. Having declined either to purchase the Company's plant or to compensate them for the loss of its business, representations were made to the Government of Ceylon which resulted in a very inadequate offer being made for the mere value of the plant. This offer your Directors declined. The Directors then appealed to the Secretary of State for the Colonies, and, ultimately, rather than sacrifice the property of the shareholders altogether, agreed to accept a sum of £2,500, equal to about one-half of the capital expended on the construction. Although the transaction was only completed in January of the present year, your Directors are advised that this item in the capital account must be shown in the accounts now presented.

Out of the revenue of the past year, a dividend is recommended of 5 per cent. free of income tax, which will absorb £8,575. 4s. and leave £806. 3s. 3d. to be carried forward.

The revenues of the Indian subsidiary companies continue to improve, although the dividends received by this Company are approximately the same as those received last year. The expenses of the Bengal Company for the past year were temporarily increased owing to a change of manager. That Company has, after payment of the same dividend as in the previous year, carried to reserve and depreciation undivided profits to the extent of Rs.23,000. The Telephone Company of Egypt has declared a dividend of 6 per cent. as usual on the Preferred shares. The China and Japan Telephone Company has had a better year, and the accounts point to an increased surplus over the previous year after payment of debenture interest. The Directors have agreed to extend the time for the payment of the debentures held in this Company, which fell due on December 31st last, for a further period of five years. The turnover by the electric lighting branch in India has more than doubled that of the preceding year, but the expenses incident to sending out an assistant and advertising have again caused a loss on the year's operations. The Directors believe there is room for development in this branch, but have deemed it desirable to write off all initial expenses such as those referred to which are usually spread over a term of years.

Mr. B. St. John Ackers and Mr. G. B. Frost offer themselves for re-election as Directors, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

ALTRINCHAM ELECTRIC SUPPLY (LIMITED).—The annual return to April 6th has just been filed. 25,000 shares have been taken up out of a capital of £50,000, in £1 shares, and calls amounting to 15s. per share have been made.

BIRMINGHAM ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return to March 25th has been filed. The capital is £200,000, in £5 shares, of which 30,000 have been taken up. The full amount has been called on 20,000, and £2 per share on 10,000 shares.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—The annual return to March 18th has been filed. The nominal capital is £100,500, in 14,000 Ordinary and 6,000 Preference shares of £5 each, and 500 Founders' shares of £1 each; 6,666 of the Ordinary and the Founders' shares have been issued as fully paid. The full amount has been called on the remaining 7,334 Ordinary and 6,000 Preference shares.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY (LIMITED).—The annual return to March 21st has been filed. The nominal capital is £60,000, in 5,500 Ordinary shares of £10 each, and 50 Founders' shares of £100 each. 3,384 Ordinary and all the Founders' have been taken up, and 2,250 Ordinary and the Founders' have been issued as fully paid. The full amount has been called on 1,134 shares.

EASTBOURNE ELECTRIC LIGHT COMPANY (LIMITED).—The annual return to March 30th has been filed. 1,025 Ordinary and 40 Preference shares have been taken up out of a capital of £50,000, in £10 shares, and the full amount has been called and paid.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to March 18th has been filed; 6,633 shares have been taken up out of a capital of £40,000, in £5 shares. The full amount has been called on 6,221, and £2 per share on 412 shares.

OXFORD ELECTRIC COMPANY (LIMITED).—The annual return to March 20th has been filed. Out of a nominal capital of £100,000, in £5 shares, 6,586 shares have been subscribed for, and the full amount has been called and paid.

SYNDICATE OF ELECTRICAL ENGINEERS (LIMITED).—The annual return to March 30th has been filed. Out of a nominal capital of £10,000, in 1,900 Ordinary and 100 Founders' shares of £5 each, the Founders' shares have been issued as fully paid, while £4 per share has been called on 1,007 Ordinary shares.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 30⅞d. per oz. (April 1st). Consols (2¾ per cent.) 110⅞–111 for money, 110⅞—111⅛ for account; 2½ per cent. 105—105½ (April 16th). Stock Exchange Settling Days: Consols, May 4th; Stocks and Shares Continuation Day, April 27th; Ticket Day, April 28th; Pay Day, April 29th; Mining Share Carry-over Day, April 25th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended April 12th were £868, against £779 in the corresponding week of 1895, an increase of £89. The total receipts for the half-year amount to £14,339, against £14,362 for the corresponding period of 1895, a decrease of £23.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The accounts to December 31st last show, subject to audit, a balance profit of £210,579 after payment of three dividends. The Directors now propose to distribute on the 30th inst. a final dividend of 2s. 6d. per share, together with a bonus of 4s. per share (or 2 per cent.), making a total distribution of 7 per cent. for the year. The Share Register will be closed from the 22nd to the 29th inst., inclusive.

GAS, WATER AND GENERAL INVESTMENT TRUST.—The ordinary general meeting of the shareholders in this Trust was held on Wednesday last. The Chairman (Mr. Thomas Salt) in moving the adoption of the report and accounts, referred to the connection of the Trust with the Salt Lake and Ogden Gas and Electric Light Company, and to the circumstances under which they acquired such a large holding in that Company. The Directors, however, looked forward to the future with hope. The net earnings of the Company were in 1893 £20,000, in 1894 £18,000, and in 1895 £19,000, and in the latter year the profits would have been much larger if it had not been for the unfortunate opposition which they had to contend with. The estimated net profits of the Company during the present year were £35,000. We are earning sufficient and more than sufficient to pay the dividends on the bonds. With regard to the difficulties that have arisen, I would remind you that all purchases of this kind are liable to unexpected difficulty. The motion was adopted, and a resolution enabling the Trust to hold the amount of stock possessed in the Salt Lake and Ogden Gas and Electric Light Company was afterwards passed.

GREAT NORTHERN TELEGRAPH COMPANY.—The net receipts of this Company during 1895, including the balance (£43,170. 17s. 8d.) brought forward from 1894, amount to £381,583. 2s. 8d. Deducting £85,916. 13s. 4d. towards interest on and amortisation of debentures and interim dividends (£75,000 already paid), the Board propose to distribute the balance as follows:—Final dividend (making the total dividend for the year 10 per cent.), £75,000; reserve and renewal fund, £83,333. 6s. 8d.; pension fund of the staff, £2,777. 15s. 7d.; directors' remuneration, £1,500; leaving to be carried forward, £58,055. 7s. 1d.

IMPERIAL CONTINENTAL GAS ASSOCIATION.—The Directors of this Association recommend the payment of a dividend of 5 per cent., together with a bonus of 1 per cent. for the half-year ended December 31st last.

LAZARE, WEILLER AND CIE.—An extraordinary general meeting of the shareholders of this Company was held in Paris on the 11th to confirm the resolution passed on October 28th last, increasing the capital of the Company by one million francs.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 12th inst. amounted to £1,469. The amount for the corresponding week last year was £1,243. Increase £226.

PONTYPOOL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual meeting of this Company was held on the 27th ult. at Pontypool. The Directors' report stated that the Company had obtained a Provisional Order, which gave them an extended lease of their undertaking for 42 years, but the local authority had liberty to purchase at the end of each seven years of the term. In order to provide for the cost of the Provisional Order, and to get rid of the adverse balance standing to the debit of capital account at the end of last year, it became necessary to raise additional capital. It was accordingly resolved to issue 15 debentures of £100 each, carrying interest at £5 per cent. per annum. These debentures were taken up by the Directors. Several new customers had been added to the Company's mains during the year, there being 54 customers connected, and the Directors consider that the outlook of the Company is promising. After putting £67. 10s. to renewal account there was a balance of net profit, together with the sum brought forward from last year, of £230. 4s. 3d. The Directors recommend that £50 be carried to reserve, that a dividend of £3 per cent. be declared, and that the remainder be carried forward. Mr. W. Pegler, jun., who presided, moved the adoption of the report and accounts, and gave an account of the progress made during the past year. The report and accounts were after a short discussion adopted.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow 22,500 Six per Cent. Cumulative Preference shares and 22,500 Ordinary shares of Willans and Robinson (Limited) to be quoted in the Official List.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The sale of electric current for the quarter ended March 25th (at 6d. per unit) amounted to £16,862, against £13,907 (at the same rate per unit) for the corresponding period of 1895.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended April 10th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,375.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 936. [No. 26. Vol. XXXVI.] FRIDAY, APRIL 24, 1896. PRICE SIXPENCE.

NOTES.

In another column we publish a further communication, received yesterday morning from Prof. RÖNTGEN. This, like his first famous memoir, is characterised by extreme lucidity and conciseness. The discoverer of X-rays has not as yet discovered any of the more startling properties which have been unearthed by hasty investigators scattered all over the civilised world. Prof. RÖNTGEN can find no difference in the discharge rate of positive or negative electricity, nor in the discharge rate of different bodies; and he makes no mention whatever of X-ray electrification. He has, however, made several additional observations of considerable value. Perhaps the most interesting—and we may add with all due deference to the great experimenter, the most doubtful—discovery, is, that air which has been traversed by X-rays retains the property of discharging electrified bodies. Prof. RÖNTGEN certainly explains his *modus operandi* very clearly; but it is not easy to see how he avoids ordinary convection discharge.

THE Post Office has often been able to prove that Mr. HENNIKER HEATON'S figures are nearly all wrong. He has now let it be seen that his figures of speech are even more so. In a letter to *The Times* yesterday, after stating, among other things relating to the telephone monopoly, that we are confronted with an accomplished fact and have to make the best of it, he proceeds "to contend, first, that the Government should take the mischief in embryo and grapple with the hydra before it is full-grown." For our part we would rather take the hydra in embryo and grapple with the mischief later on. But there really seems to be no call to do either if we are "confronted with an accomplished fact." Mr. HEATON might, however, be pardoned for his looseness of language if he would hold it tight until he understood a little better what he is going to talk about. His statement that there is no choice but to purchase the Telephone Company's rights at a cost of a hundred million sterling, or establish its monopoly in perpetuity, is absurd as well as untrue. Perhaps some of his parliamentary colleagues, whom he threatens to consult, will enlighten him as to what these rights will be worth on December 31, 1911.

IT is difficult to see what useful purpose Mr. A. L. FYFE expects to serve by distributing the following curious communication broadcast to the daily as well as to the technical press:—

"As I have always from practical experience contended that electric light and power can be more efficiently and economically supplied to towns and urban districts within a radius of five or six miles by using continuous currents than high-pressure alternating currents, I was, to settle as far as possible the question of danger, impelled to write to the Board of Trade for information. To my letter of inquiry they have courteously replied as follows:—'In reply to your letter of the 9th inst., I am directed by the Board of Trade to state that they have been informed of nine cases of fatal accidents to *employés* at generating or transforming stations where high-pressure alternating currents are used, but that no instances have been reported in the case of low-pressure continuous currents.' As the information received is of great public interest, I trust you will see the desirability of making this known to your numerous readers."

The regrettable accidents which have occurred in this country in connection with the employment of high-pressure alternate currents afford a ready means to unduly prejudice the public against their use, but it has been reserved to Mr. FYFE to be the first to take advantage of this opportunity. Apart from the graver aspect of this circular, it strikes us as an extremely inconsequential production. Mr. FYFE says that, being convinced that electric light and power can be distributed more efficiently and more economically within a certain radius by continuous currents than by high-pressure alternate currents, he felt impelled to write to the Board of Trade for information with regard to the *danger* of the latter. This is as if one should say: Being convinced of the superior reposefulness and breeziness of travelling by goods-trains, I felt impelled to write to the Board of Trade to inquire how many people have been killed by accidents to those horridly dangerous express trains. The accidents caused to workmen by high-pressure currents should not be burked, neither should they be employed as a means of improperly and unnecessarily alarming the non-technical public.

AN instance of a hastily-drawn inference from inadequate data is afforded by the conclusion at which the *Electric Railway Gazette*, of New York, arrives, viz., that surface railways are superior to underground railways. This generalisation is deduced from the fact that "a comparison of the cost per train mile for two years of two English electric railways, one a surface road and one an underground road, shows a difference of 3·18 cents per train mile in favour of the surface road." We do not wish it to be inferred that we believe the conclusion to be erroneous; but rather that a comparison between the expenses of the Liverpool Overhead Railway and the City and South London Railway does not justify such a conclusion. If

Digitized by Google

it ever becomes necessary either in this country or in America to accurately determine the relative merits of elevated and underground electric roads, the ultimate basis of comparison will scarcely be a heavily handicapped line, like that in the south of London, and an overhead line so admirably adapted to its work as the railway at Liverpool. Our American contemporary comments on the cost of working hydraulic elevators on an underground system, and on the freedom from smoke, soot and other discomforts when running overhead; but it has omitted to take into account the liability of overhead traffic to be hampered by bad weather. During one severe winter the repairs and other items of expense on the Liverpool line were very considerably increased by dirty weather, while on some American overhead lines even greater troubles have been encountered from this cause. There are distinct advantages in either method of construction, and each will probably find favour in this country for its special sphere of work; but their rival claims to general superiority are not to be settled off-hand by a comparison between a single example of each.

One of the most composite systems of electric power generation is that now in use on the Mount Lowe Railway, in California. There are three separate generating stations, each supplying power at a different point. One of these stations is equipped with a 250 H.P. spirit engine, worked with gasolene; another station is worked by water power, the 80 H.P. dynamo being driven by Pelton wheels; while the third station contains a 100 H.P. two-cylinder "Otto" gas engine, the gas being pipe-lined from a gas generator some eight miles away from the station. If only as an instance of how a light electric railway can be run by scraps and odds-and-ends of power, this line is of interest; but it would be of still greater interest to know whether it pays.

A student is sometimes helped to a better comprehension of a science by regarding it from a new standpoint, which, however, would not serve as a basis for a thoroughly scientific exposition. For instance, in order to avoid the primary difficulties involved in the conception of magnet poles, he might study the phenomena of magnetism from the point of view of magnetic moments; yet neither this nor the conception of poles would be the most scientific basis for the science of magnetism. In an article on "Fundamental Magnetic Units," which we publish this week, Mr. H. N. Allen seeks to assist students by expressing the elementary facts of magnetism in terms of a unit of magnetic moment. We notice, however, that Mr. Allen, in deriving his primary laws, has omitted to explain what he means by the *axis* of a magnet, and what is meant by "broadside on," although he bases his laws on these terms. Having discarded the conception of a magnet pole, it becomes necessary to define these terms independently of polarity. We suggest that he might define them in respect to the magnetic field of the magnet, as evidenced by iron filings; but we fear that in so doing he would introduce a greater number of ideas than he gets rid of.

Argon and helium appear to be still fields of research for anomalous and peculiar properties; and the latest investigations in their behaviour when submitted to electric discharge do but widen the breach which seems to exist between these and what we may term ordinary elements. In another column we give an abstract of a Paper read before the Royal Society, in which Drs. Collie and Ramsay describe their researches in this direction. We have in general refrained from leading our readers into the thick of the fight which has taken place around these two recently-discovered elements, because the battle has usually been fought on purely chemical and non-electrical grounds. Now, however, we are confronted by two or three properties of these gases of an electrical nature, which, as Drs. Collie and Ramsey observe, are somewhat inscrutable. For example, it is found that "a tube like those termed Plücker's tubes need not be filled with helium at a low pressure, but shows all the phenomena of a vacuum tube at ordinary atmospheric pressure." Again, the enormous length of spark which is produced in helium, and the unusually long though less lengthy sparks in argon, differentiate these elements quite inexplicably from ordinary gases. Yet, while at ordinary atmospheric pressure a discharge passes most readily through helium, at very low pressures the discharge passes more readily through any other gas than through helium; and a mixture of argon and helium, at low pressure, apparently will conduct the discharge almost exclusively through the argon. More will have to be discovered, as to the atomic mechanism of the electric discharge in gases, before these facts can be explained; but as it is they indicate that in argon and helium we have elements the electro-chemical properties of which are decidedly anomalous.

Horseless Carriages.—The full conditions of the *Engineer* road-carriage competition are published in its issue of the 17th inst.

Cable Interruptions and Repair:—

	Date of Interruption.	Date of Repair.
Assab—Massowah.....	March 29, 1896. ...	April 18, 1896.
Puerto Plata—Martinique	December 19, 1895. ...	—

Personal.—Mr. George G. Ward, of the Commercial Cable Company, leaves the States to-morrow for England. He takes part in the forthcoming Telegraphic Conference at Buda Pesth, which begins on June 16th.

The Centenary of the Voltaic Cell.—Como, the native town of Alessandro Volta, is going to celebrate the hundredth anniversary of the invention of the voltaic cell by an electrical congress and an electrical industrial exhibition.

The Use and Economies of Rectifiers for Arc Lighting.—A Paper on this subject is announced as being down for reading by Mr. John Hesketh, at the meeting of the Northern Society of Electrical Engineers, on May 11th.

Lord Kelvin's Jubilee.—Mr. T. C. Martin, one of the editors of the *Electrical Engineer* of New York, has been appointed to represent the American National Electric Light Association at the forthcoming jubilee of Lord Kelvin's professoriate at Glasgow.

Forthcoming Books.—*The Electrician* Company will publish shortly a New Edition of Vol. I. of Dr. J. A. Fleming's "Alternate-Current Transformer, in Theory and Practice." The first week in June, Mr. H. D. Wilkinson's book on "Submarine Cable Laying and Repairing" will be published by the same publishers.

Electric Tramways in Zurich.—The Swiss Federal Council has just sanctioned the construction of six electric tramways in Zurich and suburbs. Four of the concessions have been given

Digitized by Google

to the municipality of Zurich, one to Oerlikon and one to a private person. The system to be employed will be on all the lines the overhead trolley.

Transformer Patent Litigation in Italy.—The Corte d'Appelo of Florence, in the action of Zipernowsky-Déry-Bláthy *v.* Siemens and Halske, handed down on March 30th a demand for the examination of the translations of all foreign documents produced by Messrs. Siemens, and appointing for the examination of the same a committee composed of the following experts:—Prof. Rinaldo Fernini, professor of electrical engineering in the Polytechnic in Milan, Prof. Pietro Blaserna, professor of physics in the University of Rome, and Sig. Riccardo Arnò, instructor in electrical engineering at the Museo *Industriale* in Turin.

Röntgeniana.—So great has been the interest and curiosity aroused in Newcastle by the Röntgen phenomena that Prof. Stroud, who has been giving photographic and fluorescent screen demonstrations in the physical theatre of the Durham College of Science, has had to deliver his lecture three times, and on each occasion the theatre has been filled to overflowing. On Monday very clear slides of cases taken at the College were shown—viz., the hand of a lad containing a shot from a revolver; the wrist, elbow, knee and foot of adults; the leg of a lad who had had the tibia removed some years ago; and an excellent slide of a child's arm and hand showing partial ossification, &c.

The London Tramways Question.—We understand, says the *City Press*, that the Highways Committee of the County Council will bring up an important report on the tramways question either next Tuesday or on the following Tuesday. The offers of the syndicate have not been entertained, but the committee will report that the North Metropolitan and the London Street Tramways have jointly agreed to sell their undertakings to the Council at once, and to pay a sum for the 14 years' lease to be granted to them, equivalent to 9 per cent. on the capital outlay. The committee have also completed negotiations for leasing other tramways, which will return 5 per cent. on the capital outlay.

Electric and Oil Engine Vehicles.—At a stage in the development of horseless carriages when both electric and oil engine vehicles may be regarded as far from perfect, it may not be out of place to claim for electricity that it has at least run one experimental "'bus" about town at irregular intervals during the past ten years or so. We refer to the electric accumulator car invented and run by Mr. Radcliffe Ward. The claims of an oil motor syndicate to possess patents which "rule and control every substantial improvement in horseless carriages" have left electricity a little too completely out of account.

The Glasgow and West of Scotland Technical College.—At the last meeting of the Governors of this College, the subject of a site for new buildings for the college was gone into, and a report in favour of acquiring the site in North-street, coupling this proposal with the idea of retaining the George-street buildings was agreed to. The Chairman (Sir John Neilson Cuthbertson) stated that it was now 100 years since Prof. Anderson, of the university, founded the college. It had been deemed desirable that the centenary of the college should be appropriately celebrated, and it had been suggested that it should take place in June. Owing, however, to the Kelvin jubilee taking place then, it was now proposed that the celebration should take place in October. Lord Kelvin had consented to be of such use to them on the occasion as he could.

Niagara Falls.—Our Niagara Falls correspondent writes that a third 5,000 H.P. generator has been erected in the central station of the Niagara Falls Power Company, making the total capacity of the power house 15,000 H.P. This is to be increased by the addition of seven more generators, each of 5,000 H.P. capacity, which will bring up the total capacity to 50,000 H.P., or just one-half the total capacity of the tail-race tunnel. As yet it has not been decided how these additional generators are to be erected, but it has been rumoured that the Niagara Company has under consideration some suggestions of changes, which may eventually lead to placing the additional dynamos down in the big wheel pit, instead of in the power house, as at present. This method of erection would save the expense of the 138ft. shafts which now connect the turbines with the generators.

Flax Straw as Fuel.—With regard to the use of flax straw as fuel in the electric light plant at Watertown, U.S.A., the manager of the electric light works writes as follows to the *Electrical Engineer* of New York:—

"Our location here, so far from the coal fields of Iowa and Illinois results in transportation charges being so great as to prohibit the use of coal in this business with profit. Soft coal will cost from $3.50 to $6.50 per ton on cars here for the various qualities, from Iowa slack to the high-grade Eastern coals; and wood ranges from $3 per cord for soft wood to $4 for hard on cars. We can buy flax straw in abundance delivered at the plant for $1 per ton, and consider that two tons of straw is equivalent to a ton of the best coal. We have no special arrangement for using the straw The same furnace and boiler are in service, as when burning any other fuel, only that we have constructed sheet-iron chutes to the furnace doors with flaring approaches. By keeping the chutes full of straw and gradually working it into the furnace as consumed, we avoid the necessity of constantly opening and closing the furnace doors. The straw is delivered to us loose, and burned in that same condition. It, of course, requires pretty close attention, yet, after all, does not burn away as rapidly as one would suppose. The fibre in the straw makes an intense heat."

The Government and the Metric System.—In the House of Commons on Monday evening Mr. Arnold Forster asked the First Lord of the Treasury whether, in view of the fact that the metric system of weights and measures had recently been adopted by Turkey, Russia and Japan, and was now in use in all the civilised countries in the world with the exception of the British Empire and the United States of America, and in view of the fact that metric measurements had already been adopted with respect to the ton and for all purposes of pharmaceutical dispensing in the United States, Her Majesty's Government would take immediate steps to give effect to the practically unanimous recommendation of the Committee on the Metric System with the object of placing this country on a level with other civilised nations in the matter of weights and measures. In reply Mr. Balfour said that the recital of facts in the question was, he believed, correct; but he did not think it would be within the range of practical politics to impose by law on the inhabitants of this country so great a change in their ordinary habits as would be involved in giving effect to the recommendation of the Committee on the Metric System.

Electric Traction for Glasgow.—At the last meeting of the Sub-Committee of the Glasgow Corporation on tramway motors, the report upon mechanical motors drawn up by Councillor Crawford and Mr. John Young, general manager of the Corporation Tramways, from investigation on the Continent, was submitted. In carrying out the remit made to them, the two gentlemen named spent three weeks in making an inspection of a number of the chief mechanical methods of tramway traction on the Continent. In their general remarks the deputation report that the overhead system is admitted to be both best and cheapest, and in their opinion the overhead system can be extended over all existing routes in Glasgow without any disadvantage, the one great, and practically the only serious, objection being the appearance of the wires. Starting with considerable sympathy for that objection, the deputies say that what they have seen has quite removed it from their minds. The wires, where the system is carried out in the most approved manner, give only the very slightest offence to the eye, and a few hours' familiarity removes the objection entirely. The report favours the system of span wires across the streets for the support of the trolley wires, fixing the span wires to the buildings where practicable.

The Three-Wire Patent Prolongation.—At the last meeting of the Bradford Electricity Committee the Town Clerk reported that the joint objections of the interested bodies opposing the application for the prolongation of the Hopkinson three-wire patent had been formulated and duly lodged with the Privy Council. The notice of opposition contains ten clauses of objection. In the first place it is contended that the inventor and patentee has already received full and adequate remuneration, or if he has failed to do so has himself to blame. It is also alleged that the invention is not the only method of distributing electricity by three or five wire system, and that the Westinghouse Company acquired the patent "as a trading

Digitized by Google

speculation," and not to assist the inventor, and that if they have not received adequate remuneration that affords no ground for the extension sought. The objectors further urge that the Westinghouse Company have already received full and adequate remuneration for the said alleged invention, or if they have not done so, their failure is due to negligence and refusal to grant licences on reasonable terms. It is also asserted that if the petitioners had exacted royalties from or made arrangements with all users, in the same manner or of the same nature as they have exacted from or made with the objectors, they would have realised a very much larger profit than they have. The objectors and others accepted licences under the patent, and paid large sums by way of royalty in respect thereof, on the faith that the term of the patent would expire on July 27, 1896, and they contend that the alleged invention is not of such special or exclusive merit or public utility as to be sufficient justification for any extension of the term granted by the said letters patent.

The Trans-Australian Line.—Referring to a recent temporary interruption of this line the *New Zealand Herald* says: "The cable has been working fairly well for some time, but it may be noted that breaks have occurred at Alice Springs more frequently than at any other part of the whole connection with Europe. Alice Springs is the central station of the line. It is on the edge of the southern tropic, in the McDonnell ranges, at an elevation of above 1,900ft. above the sea level. For a considerable distance the line follows the track of the Australian explorer, John McDouall Stuart. It was in 1870 that the South Australian Government were committed to the completion of a telegraph line, nearly 2,000 miles long, through a difficult and dry country, which was wholly unoccupied by white men for a distance of 1,400 miles. Between Port Augusta and latitude 26deg., a distance of 600 miles, there was practically no serviceable timber. In the unoccupied stretch of country, there were no tracks for the teams, and all the wires, insulators, &c., had to be carted, besides food for the men and building materials for the stations. The construction parties for the most difficult and remote parts of the work started from Adelaide at the end of August, and the party which had to put up the most distant section did not reach the scene of their operations till May 24th of the following year. In the dry country between the Katherine and Daly Waters wells had to be sunk before the cartage could proceed. Then followed a wet season, and the flooded country became impassable. One of the first messages to Adelaide from Alice Springs conveyed the news that the man who was to have had charge of the station had perished for want of water on his way up the country. The work was completed in November, 1872. The cost of the line up to the end of 1883, including replacing the wooden poles by iron poles, was £479,174. The whole of the line is patrolled once a month, and so perfect is the insulation that messages are transmitted between Adelaide and Port Darwin, with, as a rule, only one automatic translation, namely, at Alice Springs. The stations in the interior are substantial stone buildings, well supplied with water. The operators and linesmen have to be supplied with rations from Adelaide, which are sent up every year."

Boiler Explosion at Bankside.—Mr. Howard Smith, barrister, and Mr. J. H. Hallett, consulting engineer, the commissioners appointed by the Board of Trade under the Boiler Explosion Acts, 1880-1892, held an investigation on 15th, 16th and 17th inst., at the Bricklayers' Arms, Southwark, into the circumstances attending the explosion of a boiler at the Bankside station. The Board of Trade was represented by Mr. K. E. K. Gough, and Mr. Forman appeared as counsel for the City of London Electric Lighting Company. About 6 p.m. on February 25th last there was a rush of steam and hot water in the stokehold, whereby Peacock, a fireman, was badly scalded. He died on the following morning at Guy's Hospital. The commissioners found that the explosion was caused by the down-take water circulating tubes having become plugged up at the drum end, whereby the water was prevented from finding its way to the horizontal tubes, which became distorted through overheating, and in consequence a heavy strain was set upon the cast-iron headers, which they were unable to resist; that the boiler was last cleaned out in August, 1895, and was set to work again on October 6th, in the same year, and had, since that date, steamed 881¼ hours, had been banked 1,950½ hours, and had been off for 528 hours. The commissioners were of opinion that the explosion proved beyond all doubt that the boiler was not sufficiently cleaned after August, 1895, and stated that it was clear that it was not safe to work boilers fed with this water without frequent internal examinations unless steps were taken to free it of the solid matter it contained before it was introduced to the boilers. Having regard to the fact that it had been determined by competent engineers, who advised the Company that these boilers should be thoroughly cleaned out after 2,000 hours' steaming, and that in every case they had been subjected to that operation before the 2,000 hours had elapsed, and that the engineers had acted to the best of the knowledge which they then possessed and had honestly acted on the opinion which they had formed, that the period within which they had directed that the boiler should be cleaned was sufficient to allow an ample margin for safety, which opinion was confirmed by that of independent skilled witnesses, the Court found that neither the City of London Electric Lighting Company nor any of their *employés* were to blame for the explosion, and made no order as to costs.

Recent Chemical Progress.—Prof. Dewar prefaced his first Royal Institution lecture on this subject by saying that, as in the past there had been ages which we now describe as the stone age, the bronze age, and the iron age, so in the future the times we live in would be styled the chemical age. The position of a nation could be judged by the progress it has made in the science of chemistry and its applications to the industrial arts, and though Germany was the home of chemistry, Russian chemists were now to be found in the front rank, and no one could say which of the two nations would take the lead. The lecturer then referred to the advances which have been made in the means for obtaining and measuring high temperatures since he had last delivered addresses on the subject in 1879 to 1880, and stated that the crucible invented by Sir William Siemens was the first application of the electric arc to metallurgical purposes. Moissan's electric furnace, which was an improvement on this, enabled us to obtain a temperature of about 3,000°C., or a temperature one-third hotter than could be obtained in any ordinary furnace. With this high temperature carbon could be made to form definite compounds termed carbides with many of the metals with which it was previously impossible to make it combine, and amongst others the carbides of lithium, calcium, strontium, barium, aluminium, cerium, yttrium, thallium, and uranium had been prepared. The appearance of these bodies was not attractive, and in the dry state they were uninteresting. Immersed in water, however, they at once exhibited activity, and gave off hydrocarbon gases. Carbide of calcium was now manufactured by the ton in the furnace, and gave off the new illuminating gas acetylene (C_2H_2), which was eight times more brilliant than coal gas. This gas was first discovered by Sir Humphrey Davy's nephew in 1837, when he was working at the Royal Institution, and was called carburetted hydrogen. At red heat acetylene yielded benzol, the wonderful coal tar product from which we obtained all the aniline dyes and many other useful products. Both acetylene and benzol had hitherto only been formed by long and costly processes, but now by means of the electric furnace we obtained them by direct synthesis. In connection with this manufacture it might be mentioned that the presence of as little as 3 per cent. of magnesium in the limestone hindered the formation of acetylene. Carbide of cerium, which was a very expensive metal, for it cost about eighteenpence a grain, yielded petroleum when treated with water, which seemed to confirm Mendelieff's hypothesis concerning the oil wells at Baku. About 20 years ago Mendelieff was laughed at for suggesting that the continuous flow of the oil was owing to its continuous formation deep down in the earth due to the action of water on the metallic carbides, and to-day we found that the carbide of cerium, which is one of the heavy metals supposed to exist in that situation, *does* yield petroleum when treated with water.

ELECTROMAGNETIC THEORY.—LXXXV.*

BY OLIVER HEAVISIDE.

(*Continued from page 719.*)

§ 341. In order to convert the operational solution to a series of Bessel normal functions we naturally use in the first place the form (32), involving the convergent functions We are virtually in possession of the unit impulsive function. —that is, by putting $h=pQ$, and developing by the expansion theorem, the result is a formula showing how the charge Q, initially at y, subsequently behaves. But to allow of this development, (32) should be a rational differential equation. Two necessary failures are obvious. First, if $l=\infty$, which does away with the infinite series of reflections, leaving in general only two waves, these waves themselves constitute the practically significant result. The set of normal functions with distinctly separated periods or rates of subsidence no longer exists, although the series of normal functions appropriate when l is finite has its ultimate representative in a definite integral, the limit of the series. Secondly, if either of the terminal operators be irrational, we have a similar failure, and a similar resulting definite integral.

But, assuming that l is finite, and that both the terminal operators are rational (as well as Y, Z in the circuital equations), we may confidently expect that the operational equation (32) contains p the time differentiator rationally, in spite of the presence in the functions concerned of q^m, where m may be fractional, or of $\log q$ in some cases. As a matter of fact, such irrationalities are inoperative by appearing in a suitable manner for cancellation. Thus, in (32) it will be found that r and s both have the factor q^{2m}, whilst I_m has q^m, and I_{-m} has q^{-m}. So the numerator and denominator in (32) both have the factor q^{2m}, and, therefore, (32) is a rational function of q^2, itself a rational function of p.

This being true for any value of m, it follows that in the case of m being integral, when we need to employ the 0/0 form of the K_m function, which brings in the logarithm of q, there is a similar elimination of this logarithm. It goes out in this fashion :—$\log \frac{1}{2}ql - \log \frac{1}{2}q\lambda = \log l/\lambda$. In the results we have only logarithms of numbers.

The alternative form of (32), in terms of I_m and K_m instead of I_m and I_{-m}, is got by using

$$\mathrm{I}_{-m} = \mathrm{I}_m + \mathrm{K}_m \sin m\pi \tag{49}$$

in (32). This brings us to

$$\mathrm{V}_1 = \frac{\frac{1}{2}\pi Zh}{x^m y^m} \frac{(\mathrm{I}_{mx} - f\mathrm{K}_{mx})(\mathrm{I}_{my} - g\mathrm{K}_{my})}{f-g}, \tag{50}$$

where

$$f = \frac{\mathrm{I}_{m\lambda} - \mathrm{A}\mathrm{I}_{m+1,\lambda}}{\mathrm{K}_{m\lambda} + \mathrm{A}\mathrm{K}_{m+1,\lambda}}, \tag{51}$$

and g is got by turning λ to l and A to $-\mathrm{B}$. Here the convergent K_m function may be understood, though the same result is true with the divergent form.

If l is made infinite, it will be found, by using the divergent series, that g becomes either $+\infty$, or $-\infty$ according to the nature of Z_1. In either case Z_1 is impotent, and (50) reduces to

$$\mathrm{V}_1 = \frac{\frac{1}{2}\pi Zh}{x^m y^m} (\mathrm{I}_{mx} - f\mathrm{K}_{mx})\mathrm{K}_{my}, \tag{52}$$

showing just the primary wave and a reflected one. This is the form suitable for simply periodic states when fully established, as to which more later.

The conversion of (50) to normal functions is merely a formal one by the expansion theorem, but there may be a good deal of work needed sometimes to bring the result to a form suitable for calculation by such tables as exist. In general, the roots of the determinantal equation $f=g$ are complex. That is too bad. But there are important cases of a relatively simple nature. Say $\mathrm{L}=0$, retaining R, S, K finite. Then only electric energy is concerned in the "medium," whether with wires or not. If also there is only electric energy concerned at the terminals, the roots (for p) of the determinantal equation are all real and negative.

In like manner, if $\mathrm{S}=0$, retaining R, L, K finite, only magnetic energy is concerned in the medium; and if this is also the case terminally, we have again roots of the same nature. These are two extreme cases of diffusion, with infinite speed v of propagation, though the practical result may be slow enough. Also, if R, K are zero, and L, S finite, we have finite speed of propagation without waste by resistance; therefore undamped vibrations can occur. In this case the roots are $p=\pm\theta i$, where θ is real, and corresponding terms can be paired to make real vibrations. To this may be added that if R and K are not zero, but are properly balanced, we have the last case again, with attenuation due to R and K superimposed. This nearly exhausts all the applications of a relatively simple nature; though if we do away with the terminal considerations, by taking Z_0 and Z_1 to be either zero or infinity, which makes either the current or the potential vanish terminally, we can extend the matter further.

§ 342. In all such cases, it is convenient to convert the functions from I_m and K_m to the oscillating functions J_m and G_m, or perhaps to J_m and J_{-m} instead. The cases of integrality of m are perhaps most common; then it is better to use K_m or G_m, and ignore I_{-m} and J_{-m}.

The oscillating functions are got by putting $q=si$. Thus,

$$\mathrm{I}_m(qx) = i^m \mathrm{J}_m(sx), \qquad \mathrm{I}_{-m}(qx) = i^{-m}\mathrm{J}_{-m}(sx), \tag{53}$$

where

$$\mathrm{J}_m(sx) = \frac{(\frac{1}{2}sx)^m}{\underline{|0}\ \underline{|m}} - \frac{(\frac{1}{2}sx)^{m+2}}{\underline{|1}\ \underline{|m+1}} + \frac{(\frac{1}{2}sx)^{m+4}}{\underline{|2}\ \underline{|m+2}} - \ \ldots, \tag{54}$$

and J_{-m} is the same with $-m$ put for m. When the argument sx is real, this is an oscillating function, the original Bessel function in fact. But the functions involving q are more primitive.

Now as regards K_m. Use the second of (34), with $q=si$. Then,

$$\mathrm{K}_m(qx) = i^{-m}\frac{\mathrm{J}_{-m}(sx) - i^{2m}\mathrm{J}_m(sx)}{\sin m\pi}. \tag{55}$$

Here $i^{2m} = (\cos + i\sin)m\pi$. So we may write

$$\mathrm{K}_m(qx) = i^{-m}\{\mathrm{G}_m(sx) - i\mathrm{J}_m(sx)\}, \tag{56}$$

where G_m is defined by

$$\mathrm{G}_m(sx) = \frac{\mathrm{J}_{-m}(sx) - \cos m\pi\, \mathrm{J}_m(sx)}{\sin m\pi}. \tag{57}$$

Or, if we expand i^{-m} in (55) as well, we get

$$\mathrm{K}_m = \frac{\mathrm{J}_{-m} - \mathrm{J}_m}{2\sin \frac{1}{2}m\pi} - i\frac{\mathrm{J}_{-m} + \mathrm{J}_m}{2\cos \frac{1}{2}m\pi}. \tag{58}$$

But the form (56) is the one to take note of.

So now, by the use of (53), we convert the equation (32) to

$$\mathrm{V}_1 = \frac{\frac{1}{2}\pi Zh}{x^m y^m} \frac{(\mathrm{J}_{mx} - \rho\mathrm{J}_{-mx})(\mathrm{J}_{my} - \sigma\mathrm{J}_{-my})}{\rho - \sigma}, \tag{59}$$

where

$$\rho = \frac{\mathrm{J}_{m\lambda} + \mathrm{A}'\mathrm{J}_{m+1,\lambda}}{\mathrm{J}_{-m\lambda} - \mathrm{A}'\mathrm{J}_{-m-1,\lambda}}, \qquad \mathrm{A}' = \frac{\lambda^n s \mathrm{Z}_0}{\mathrm{Z}}, \tag{60}$$

and σ is got by turning λ to l and A' to $-\mathrm{B}'$ in ρ. We have $\mathrm{A}=i\mathrm{A}'$, and $\mathrm{B}=i\mathrm{B}'$.

Also, by the use of (56), we convert the alternative equation (50) to the form

$$\mathrm{V}_1 = \frac{\frac{1}{2}\pi Zh}{x^m y^m} \frac{(\mathrm{J}_{mx} - \alpha\mathrm{G}_{mx})(\mathrm{J}_{my} - \beta\mathrm{G}_{my})}{\alpha - \beta}, \tag{61}$$

where

$$\alpha = \frac{\mathrm{J}_{m\lambda} + \mathrm{A}'\mathrm{J}_{m+1,\lambda}}{\mathrm{G}_{m\lambda} + \mathrm{A}'\mathrm{G}_{m+1,\lambda}}, \tag{62}$$

and β is got by turning λ to l and A' to $-\mathrm{B}'$ in α.

Observe, comparing the forms of (50) and (61), and of α and f, that the transformation is the same in effect as turning I_m to J_m and K_m to G_m, with the change from A to A'. Similarly, as regards the transformation from (32) to (59). The symbol i does not appear in (50), but when we put $q=si$, it appears in K_m through (56), and therefore in f and g. It cancels out on further reduction, and then the strikingly similar form (61) results. That i ought to cancel out is clear enough, because since (50) is rational in q^2, (61) must be rational in s^2. Nevertheless the way the symbol i goes out is somewhat remarkable, depending, as it does, upon the

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

existence of two boundaries. It will not take place when there is only one. Say $l=\infty$, then g^{-1} is zero, and the form (52) results. Put $q=si$, and we do not get a result rational in s^2, and we ought not.

In connection with this, there is sometimes a bit of hocus pocus. If we like we may make the functions J_m and G_m the primary objects of attention, so that

$$V_1=(J_{mx}-\alpha G_{mx})X \qquad (63)$$

is the initial form of operational solution, s^2 having the meaning $-YZ$. Determining α and X by the conditions as regards h and terminally, we shall arrive at the result (61). This may, in fact, be the best way to work, when the ultimate results are to be simply periodic or normal solutions, and the development of waves is not in question. But there is a curious irreversibility sometimes concerned. We can always pass from the primitive I_m and K_m to J_m and G_m, but we cannot always go the other way. For instance, (61) leads to (56), by substituting $i^{-1}q$ for s, only when there are two boundaries. It fails when $l=\infty$.

For example, suppose that the condition at l is that $V_2=0$. Then $J_{mx}-\beta G_{mx}$ must vanish at l, and this shows that β must be J_{ml}/G_{ml}. Introduce some other kind of terminal condition, and we get some other form of β. But how find its value when $l=\infty$? If we have worked entirely with J_m and G_m, and know nothing of I_m and K_m, there is apparently nothing to show what β should be. For J_m/G_m, the ratio of two real oscillating functions when the argument is real, has no particular limiting value when l is infinite. Nevertheless, if we write $J_{ml}/G_{ml}=-i$, we shall come to the proper result. For it is the same as $\beta=-i$, which is correct.

The explanation has been already virtually given. It is the K_m function that is concerned alone when l is ∞; when $q=si$, then $(G_m-iJ_m)i^{-m}$ takes its place; that is, $-i(J_m+iG_m)i^{-m}$, or $\beta=-i$. But, quite independently of this determination of β, a physically-minded man, who was working in terms of J_m and G_m for convenience in the practical application, would arrive at the correct result by considering the flux of energy. In a simply periodic state produced between the source at y and infinity, with no reflection, the flux of energy must be outward. This necessitates $\beta=-i$.

§ 343. We know that the operational solution in terms of the divergent H_m and K_m is equivalent to that in terms of I_m and and I_{-m} or of I_m and K_m. Therefore, the same transformation $q=si$ in the divergent operational formula should lead to a result equivalent to that in terms of J_m and G_m. For distinctness, put a bar over the divergent functions. Then, $q=si$ in H_m, K_m produces

$$\overline{H}_m(qx)=i^m\{\overline{J}_m(sx)-i\overline{G}_m(sx)\}, \qquad (64)$$

$$\overline{K}_m(qx)=i^{-m}\{\overline{G}_m(sx)-i\overline{J}_m(sx)\}, \qquad (65)$$

when $\overline{J}_m$ and $\overline{G}_m$ are given by

$$\overline{J}_m(sx)=\left(\frac{2}{\pi sx}\right)^{\frac{1}{2}}\Big(P\cos+Q\sin\Big)(sx-\tfrac{1}{4}\pi+\tfrac{1}{2}m\pi), \qquad (66)$$

$$\overline{G}_m(sx)=\left(\frac{2}{\pi sx}\right)^{\frac{1}{2}}\Big(-P\sin+Q\cos\Big)(sx-\tfrac{1}{4}\pi+\tfrac{1}{2}m\pi), \qquad (67)$$

in which P and Q are the divergent functions

$$P=1-\frac{(1^2-4m^2)(3^2-4m^2)}{1.2(8sx)^2}\Big(1-\frac{(5^2-4m^2)(7^2-4m^2)}{3.4(8sx)^2}\Big(1-\ldots, \qquad (68)$$

$$Q=\frac{1^2-4m^2}{1.(8sx)}\Big(1-\frac{(3^2-4m^2)(5^2-4m^2)}{2.3(8sx)^2}\Big(1-\frac{(7^2-4m^2)(9^2-4m^2)}{4.5(8sx)^2} \qquad (69)$$

The G_m formula is obtained from the J_m one by turning sin to cos and cos to $-$ sin. When x is large, $P=1$ and $Q=0$, so

$$\overline{J}_m(sx)=\left(\frac{2}{\pi sx}\right)^{\frac{1}{2}}\cos(sx-\tfrac{1}{4}\pi+\tfrac{1}{2}m\pi), \qquad (70)$$

$$\overline{G}_m(sx)=-\left(\frac{2}{\pi sx}\right)^{\frac{1}{2}}\sin(sx-\tfrac{1}{4}\pi+\tfrac{1}{2}m\pi), \qquad (71)$$

show the ultimate nature of the oscillating functions at a considerable distance from the origin. They behave just like $\cos sx$ and $\sin sx$, but with amplitudes varying inversely as the square root of the distance from the origin.

J_m and $\overline{J}_m$ are equivalent when sx is real, and so are G_m and $\overline{G}_m$. The first was proved by Sir G. Stokes; the second I find in Gray and Mathew also, though somewhat difficult to recognise, owing to the use of several forms of the second function. It has been standardised in different ways, some of which are very inconvenient.

If in the H_m, K_m formula (22) we make the changes, according to (64), we shall arrive at (61) above precisely, only with $\overline{J}_m$ instead of J_m, and $\overline{G}_m$ instead of G_m. This alone would not prove the equivalence of the convergent and divergent oscillating functions. For example, if we put $\overline{H}_m=2i^m\overline{J}_m$ in (22), instead of the proper form (64), we shall still arrive at the same result (61).

There is, in fact, an essential difference between the two divergent functions $\overline{H}_m$ and $\overline{K}_m$. Say $m=0$, for instance. This is an important case. We do have $\overline{H}_m=2I_m$ when qx is real and positive. But it is not an equivalence when $q=si$, and sx is real. One makes $\overline{J}_0-i\overline{G}_0$. The other makes $2J_0$. On the other hand, $\overline{K}_0=\overline{G}_0-i\overline{J}_0$, and $K_0=G_0-iJ_0$; and we have $\overline{K}_0=K_0$, both when q is real positive, and when s is real positive.

§ 344. I have given elsewhere an algebraical explanation of the distinction. But it will be more satisfactory here to regard the matter physically. We ought to have the one agreement, and we ought to have the other discrepancy, by consideration of the physics. Go back to (5), for example, expressing the initial waves, and suppose that the source h is simply periodic, and that there is no waste of energy by resistance. This makes $q=p/v$, so that if the frequency of the source is $n/2\pi$, then $q=ni/v$, and $s=n/v$. The wave to the right is then

$$V_2=\frac{K_{mx}}{x^m}E=\frac{G_{mx}-iJ_{mx}}{x^m}e, \qquad (72)$$

when E and e are simply periodic functions of the time. Or, if $e=e_0\sin nt$, then

$$V_2=\frac{G_{mx}\sin nt-J_{mx}\cos nt}{x^m}e_0. \qquad (73)$$

This represents the ultimate result of the periodic source, and the corresponding current is

$$\begin{aligned}C_1&=\frac{q}{Z}x^{m+1}(G_{m+1,x}-iJ_{m+1,x})i^{-1}e\\&=-\frac{q}{Z}x^{m+1}(J_{m+1,x}+iG_{m+1,x})e\\&=-\frac{qe_0}{Z}x^{m+1}(J_{m+1,x}\sin nt+G_{m+1,x}\cos nt).\end{aligned} \qquad (74)$$

Here $q/Z=(Y/Z)^{\frac{1}{2}}=$ constant. These solutions indicate a train of waves travelling outwards. The flux of energy is VC. Its mean value over a period is

$$(VC)_{mean}=\tfrac{1}{2}\frac{qx}{Z}e_0^2(J_mG_{m+1}-G_mJ_{m+1})_x. \qquad (75)$$

This is constant, on account of the conjugate property of J_m and G_m, which is (if the accent is d/dx)

$$J_mG'_m-J'_mG_m=\frac{2}{\pi x}. \qquad (76)$$

That is to say, there is a steady average flux of energy from the source out to infinity, and this is as it should be, because there is no barrier.

In a similar manner, the wave to the left is

$$V_1=\frac{H_{mx}}{x^m}F=\frac{(J_{mx}-iG_{mx})}{x^m}f, \qquad (77)$$

where F and f are simply periodic, and this represents a wave train travelling to the left. The flux of energy will again be found to be constant on the average, and to be directed to the left. But this state of things is an impossible one, regarded as the ultimate state, like the other. It can only exist approximately initially. Say that h is at a great distance, and the frequency is so great that very many wave lengths can exist between h and the left barrier before it is reached. Then the above solution may be nearly true in a great part of the region occupied by the disturbance. But,

* O, in P.M., Part 2.

Digitized by Google

whereas there is no barrier on the right side, there must be one on the left side, either at λ, as before, or at the origin itself. When the barrier is reached a new state of things will begin to prevail, first at the barrier, and then travelling out to infinity. Its nature will depend upon the kind of condition imposed at the barrier. It is then generally necessary to consider the second wave equation (8) as well as the first, equation (7), and superimpose them properly.

If the barrier should be such as not to take in energy continuously, the result between the barrier and the source must be a stationary vibration, involving no average flux of energy. The case $m=0$ is peculiar, when the barrier is at the origin. There can be no current there, and no flux of energy. So to the inward wave $H_{0x}.e$ or $(J_{0x}-iG_{0x})e$, add the outward wave $(G_{0x}-iJ_{0x})ie$. The result is $2J_{0x}e$, that is, $2I_{0x}e$. Here $2J_{0x}.e$ represents the ultimate stationary vibration which replaces the preceding state $(J_{0x}-iG_{0x})e$. The operator H_{0x} is valid at first, and then, later, the equivalent $2I_{0x}$, as soon as the origin is reached. We see that we have no right to expect that the property $H_m=I_m+I_{-m}$ should be true when s is real as well as when q is real.

The matter is made plainer by considering h to be steady, beginning at the moment $t=0$. The inward wave from h at y is calculable from H_{0x} until the origin is reached. The result is convergent. But after that, that is, after the moment $t=y/v$, it is only a partial solution, valid between y and the front of the return wave. In the region occupied by the return wave and the primary, we can calculate the wave by $2I_{0x}$ instead of H_{0x}. The two forms of solution become identical at the junction. This matter will be made plainer by one or two special examples. The present remarks are directed to the cause of the failure of $H_m=I_m+I_{-m}$ when $q=si$ and s is real, a cause which is not operative when the K_m function is in question.

§ 345. So long as the barrier at λ is at a finite distance from the origin, there is no interference with the power of imposing any terminal condition $V=-Z_0C$ of the usual nature, because the functions concerned have finite values. But when $\lambda=0$, there are some noteworthy peculiarities. We know that in one special case (viz., $n=0$, or $m=-\frac{1}{2}$), that of plane waves in a homogeneous medium, we may impose any condition at the origin. We have also observed that in another case ($n=1$, or $m=0$), that of cylindrical waves in a homogeneous medium, or of plane waves in a medium in which the constants vary as the first (or inverse first) power of the distance from a fixed plane, the Z_0 condition is impotent, because there can be no current at its place of application under any finite voltage. We have, therefore, to inquire when in general the Z_0 condition is potent, and when impotent. This is to be done by examination of the limiting form assumed by a in (22), or by r in (32) or by f in (50), when λ is made zero, under different circumstances. This is rather tedious mathematically, from the absence of luminosity. But we can throw some light upon the matter physically, and see that the mathematical results are justifiable.

Under what circumstances can there be a current at the origin when under an impressed voltage? Plainly the resistance must not be infinite. Now the resistance per unit length is Rx^{-n}, which is infinite or zero at the origin according as n is + or −. But the resistance per unit length is not (under the circumstances) the same as the resistance of unit length at the origin. The resistance of the length from 0 to x is $\int_0^x Rx^{-n}dx$. This is finite when n is negative, and also when it is positive, up to $n=1$, when it becomes infinite, and remains infinite for all greater values of n. Here the distance 0 to x may be a very little bit at the origin. So we see that there can be no current there when n is 1 or >1. This is true also as regards the source h. The terminal condition, if applied, must be impotent when n is 1 or >1.

Next, consider the permittance of a little bit from 0 to x at the origin. This is $\int_0^x Sx^n dx$, which is finite when n is positive, and also when n is negative, down to $n=-1$, when it becomes infinite, and remains infinite for greater negative values of n. If, then, n is -1 or <-1, no finite charge can raise the potential at the origin above zero. The terminal condition must be again impotent.

Thirdly, when n is between -1 and $+1$, both the resistance and the permittance of the little bit at the origin are finite; V and C may then have any ratio, and the Z_0 condition of the usual kind is operative if applied.

In the first case, we require to use I_{mx} only, when m is +, or $n=$ or >1. This makes C be zero at the origin. In the next case, when n is -1 or <-1, we must use I_{-mx}, m being -1 or <-1. This makes V be zero at the origin. In the intermediate case both functions will or may occur, according to the nature of Z_0; that is, both I_m and I_{-m}, or I_m and K_m, or J_m and G_m, if we use the oscillating functions. The last is rather remarkable, it leads not only to expansions of the form ΣAJ_{mx}, but also the form $\Sigma C(J_{mx}-\alpha G_{mx})$, when the origin is one of the barriers.

(To be continued.)

FUNDAMENTAL MAGNETIC UNITS.

By H. N. Allen (University of Nebraska).

It is possible to avoid the assumption, tacit or otherwise, of magnetic fluids covering the ends of the magnets, by defining the unit magnet and the unit magnetic field without introducing, as a temporary expedient, the idea of a magnetic pole.

The definitions rest on laws determined directly with the torsion balance, the bifilar magnetometer, the vibration magnetometer, or the deflection magnetometer.

The first law is, that in a uniform field the torque on a suspended magnet is proportional to the magnetic moment of the magnet, the field intensity, and the sine of the angle between the axis of the magnet and the direction of the field. The second is that when one magnet is placed "broadside on" to another, the distance between them being great compared with their lengths, the maximum torque acting on the second is proportional to the magnetic moment of each magnet, and inversely proportional to the cube of the distance between centres. If the first is placed end on to the second, the maximum torque, on this latter, is twice as great as in the former case.

The definitions are framed in such a way as to convert the above proportions into equalities, and lead to exactly the same units of magnetic moment, and of field intensity, as are obtained in the ordinary way by means of unit poles.

Definition of Unit Magnetic Moment.—If two very short magnets, of unit magnetic moment, are placed one centimetre apart, with the axis of one of them pointing along the line joining them, and that of the other at right angles to this line, the torque tending to twist the first parallel, but opposite to the second is unity. A couple of magnitude two tends to make the second parallel to the first.

In other words B being broadside on to A, the torque on A is unity, and A being end on to B, the torque on B is two units.

Definition of Unit Magnetic Field.—The unit magnetic field intensity is that of a field in which a unit elementary magnet, with its axis at right angles to the direction of the field, is acted on by unit torque, tending to make it parallel to the field.

The main difficulties about a method of treatment founded on these definitions are to obtain the connection between induction and intensity of magnetisation in a magnetic substance, and to define clearly the idea of magnetomotive force, or difference of magnetic potential.

It is possible, in both cases, to use the electrostatic analogy, defining the unit electrostatic doublet—to correspond to the magnet of unit magnetic moment—and showing how, in the outside field, the tubes of electrostatic force, due to the doublet, are geometrically the same as the magnetic tubes due to a magnet, the moment of which has the same numerical value. It can be shown in this way by assuming that the tubes of magnetic induction form closed circuits, that the induction in the central parts of a long thin permanent magnet is $\mathbf{B}=4\pi\mathbf{I}$, and if a field $\mathbf{H}$ is present in addition, having the same direction as $\mathbf{I}$, $\mathbf{B}=\mathbf{H}+4\pi\mathbf{I}$.

Digitized by Google

Problems which have to do with magnetomotive force and magnetic flux may be treated in the same way as similar problems concerning electromotive force and current. This is, of course, the constant practice in the more advanced portions of the subject, and produces just as good results in the simpler cases.

The case of a long straight wire conveying a current C may be taken as an example. The magnetic field intensity at a distance r from the axis of the wire is $\mathsf{H} = \frac{2C}{r}$. If the current is supposed to run down into the plane of the paper, the lines of force will run round the wire in circles in clockwise direction. The flux between two cylinders, concentric with the wire, with radii r and $r + dr$, will be, for unit length of the cylinders, $\mathsf{H}\,dr$.

The reluctance of the wire, calculated just like the resistance of a metal ring for electricity, will be $\frac{l}{dr} = \frac{2\pi r}{dr}$. The specific reluctance is unity for air. Thus the magnetomotive force round the tube, which by the "Ohm's law" of magnetic flux is equal to the flux multiplied by the reluctance, will be $\frac{2\pi r}{dr} \times \mathsf{H}\,dr = \frac{2\pi r}{dr} \times \frac{2C}{r} \times dr = 4\pi C$, which is independent of r. Thus $4\pi C$ planes, radiating from the axis of the wire, with equal angles between them, will represent the surfaces of equal magnetic potential, and the magnetomotive force along the induction tubes, between the successive planes, will be unity.

If a long concentric cylinder of iron surrounds the wire, the induction will be $\mathsf{B} = \mu\mathsf{H} = \frac{2\mu C}{r}$. The flux round the ring described above will be $\mathsf{B}\,dr = \frac{2\mu C\,dr}{r}$. The reluctance of the circuit will be $\frac{2\pi r}{\mu\,dr}$, since μ, the permeability, is the reciprocal of the specific reluctance.

Thus the magnetomotive force, in this case, round the circuit, will be $\frac{2\mu C\,dr}{r} \times \frac{2\pi r}{\mu\,dr} = 4\pi C$, or exactly the same as before.

In case the tube is linked n times with the wire, or is due to n wires conveying the same current, about which it forms a closed loop, the magnetomotive force round the circuit will be $2\pi C n$.

The case of a solenoid may be taken in illustration. Some of the induction tubes, in the interior, will run the whole length of the solenoid, and complete their circuit outside. If there are n turns in the spiral, such a tube will be linked with the wire n times, and the total magnetomotive force round it will be $4\pi C n$. If the solenoid is very long indeed, nearly all of this will be used in sending the tube through the interior of the solenoid, and very little in sending it back outside; for the reluctance of this last part of the magnetic circuit is very small, the sectional area of this part of the tube being enormous. Thus, at the centre of such a long solenoid the magnetomotive force per unit length will be $\frac{4\pi C n}{l}$, or $4\pi C m$, where m is the number of turns per unit length.

Take a centimetre cube, two of the faces of which are magnetic equipotential surfaces. Since the specific reluctance of air is unity, the reluctance of this cube is unity, and the flux through it, being equal to the magnetomotive force divided by the reluctance, will be $4\pi C m$. This flux through a square centimetre in the solenoid is, of course, the magnetic field intensity, so that $\mathsf{H} = 4\pi C m$.

It almost seems as though this method of treating elementary problems would be a help in clearly bringing out the meaning of the term magnetomotive force. The more advanced problems of dynamo design are often somewhat complicated and require approximations which are apt to make the student regard the method as a rough engineer's device which gives results but has not a solid scientific foundation.

While there can be no doubt that the ordinary mode of treatment of magnetic problems, by a temporary assumption of the existence of magnetic poles, is perfectly logical, it seems as though a system, founded on what can be observed directly, and on our real conceptions of the nature of magnetism, must have many advantages, if it is not too complicated. Whether this is the case with the definitions here given, must be left to the judgment of teachers and other interested persons.

ON A NEW FORM OF RADIATION.*

BY PROF. WILHELM KONRAD RÖNTGEN.

As my investigations will have to be interrupted for several weeks, I propose in the following Paper to communicate a few new results.

§ 18. At the time of my first communication it was known to me that X-rays were able to discharge electrified bodies, and I suspected that it was X-rays, not the unaltered cathode-rays which got through his aluminium-window, that Lenard had to do with in connection with distant electrified bodies. When I published my researches, however, I decided to wait until I could communicate unexceptional results. Such are only obtainable when one makes the observation in a space which is not only completely protected against the electrostatic influences of the vacuum tube, leading-in wires, induction-coil, &c., but which is also protected against the air coming from the vicinity of the discharge apparatus. To this end I made a box of soldered sheet zinc, large enough to receive me and the necessary apparatus, and which, even to an opening which could be closed by a zinc door, was quite air-tight. The wall opposite the door was almost covered with lead. Near one of the discharge apparatus placed outside, the lead-covered zinc wall was provided with a slot 4 cm. wide, and the opening was then hermetically closed with a thin aluminium sheet. Through this window the X-rays could come into the observation-box. I have observed the following phenomena:—

(*a*) Positively or negatively electrified bodies in air are discharged when placed in the path of X-rays, and the more quickly the more powerful the rays. The intensity of the rays were estimated by their effect on a fluorescent screen or on a photographic plate. It is all the same whether the electrified bodies are conductors or insulators. Up to the present I have discovered no specific difference in the behaviour of different bodies with regard to the rate of discharge, and the same remark applies to the behaviour of positive and negative electricity. Nevertheless, it is not impossible that small differences exist.

(*b*) If an electrical conductor is surrounded by a solid insulator, such as paraffin, instead of by air, the radiation acts as if the insulating envelope were swept by a flame connected to earth.

(*c*) If this insulating envelope is closely surrounded by a conductor connected to earth, which should like the insulator be transparent to X-rays, the radiation, with the means at my disposal, apparently no longer acts on the inner electrified conductor.

(*d*) The observations described in *a*, *b* and *c* tend to show that air traversed by X-rays possesses the property of discharging electrified bodies with which it comes in contact.

(*e*) If this be really the case, and if, further, the air retains this property for some time after the X-rays have been extinguished, it must be possible to discharge electrified bodies by such air, although the bodies themselves are not in the path of the rays.

It is possible to convince oneself in various ways that this actually happens. I will describe one arrangement, perhaps not the simplest possible. I employed a brass tube, 3cm. in diameter and 45cm. long. A few centimetres from one end a portion of the tube was cut away and replaced by a thin sheet of aluminium. At the other end an insulated brass ball fastened to a metal rod was led into the tube through an air-tight gland. Between the ball and the closed end of the tube a side tube was soldered on, which could be placed in communication with an aspirator. When the aspirator was worked the brass ball was surrounded by air, which on its way

* Second communication. For the first communication to the Würzburg Physico-Medical Society see *The Electrician*, January 24th, p. 415.

Digitized by Google

through the tube went past the aluminium window. The distance from the window to the ball was over 20cm. I arranged the tube in the zinc box in such a manner that the X-rays passed through the aluminium window at right angles to the axis of the tube, so that insulated ball was beyond the reach of the rays in the shadow. The tube and the zinc box were connected together; the ball was connected to a Hankel electroscope. It was seen that a charge (positive or negative) communicated to the ball was not affected by the X-rays so long as the air in the tube was at rest, but that the charge immediately diminished considerably when the aspirator caused the air traversed by the rays to stream past the ball. If the ball by being connected to accumulators was kept at a constant potential, and if air which had been traversed by the rays was sucked through the tube, an electric current was started as if the ball had been connected with the wall of the tube by a bad conductor.

(*f*) It may be asked in what way the air loses this property communicated to it by the X-rays. Whether it loses it as time goes on, without coming into contact with other bodies, is still doubtful. It is quite certain, on the other hand, that a short disturbance of the air by a body of large surface, which need not be electrified, can render the air inoperative. If one pushes, for example, a sufficiently thick plug of cotton wool so far into the tube that the air which has been traversed by the rays must stream through the cotton wool before it reaches the ball, the charge of the ball remains unchanged when suction is commenced. If the plug is placed right in front of the aluminium window the result is the same as if there were no cotton wool, a proof that dust particles are not the cause of the observed discharge. Wire gauze acts in the same way as cotton wool, but the meshes must be very small and several layers must be placed one over the other if we want the air to be active. If the nets are not connected to earth, as heretofore, but connected to a constant-potential source of electricity, I have always observed what I expected; however, these investigations are not concluded.

(*g*) If the electrified bodies are placed in dry hydrogen instead of air they are equally well discharged. The discharge in hydrogen seems to me somewhat the slower. This observation is not, however, very reliable on account of the difficulty of securing equally powerful X-rays in successive experiments. The method of filling the apparatus with hydrogen precluded the possibility of the thin layer of air which clings to the surface of the bodies at the commencement playing an appreciable part in connection with the discharge.

(*h*) In highly-exhausted vessels the discharge of a body in the path of the X-rays takes place far slower—in one case it was, for instance, 70 times slower—than in the same vessels when filled with air or hydrogen at atmospheric pressure.

(*i*) Experiments on the behaviour of a mixture of chlorine and hydrogen, when under the influence of the X-rays, have been commenced.

(*j*) Finally, I should like to mention that the results of the investigations on the discharging property of the X-rays, in which the influence of the surrounding gases was not taken into account, should be for the most part accepted with reserve.

§ 19. In many cases it is of advantage to put in circuit between the X-ray producer and the Rhumkorff coil a Tesla condenser and transformer. This arrangement has the following advantages:—Firstly, the discharge apparatus gets less hot, and there is less probability of its being pierced; secondly, the vacuum lasts longer, at least this was the case with my apparatus, and thirdly, the apparatus produces stronger X-rays. In apparatus which was either not sufficiently or too highly exhausted to allow the Rhumkorff coil alone to work well, the use of a Tesla transformer was of great advantage.

The question now arises—and I may be permitted to mention it here, though I am at present not in a position to give an answer to it—whether it be possible to generate X-rays by means of a continuous discharge at a constant discharge potential, or whether oscillations of the potential are invariably necessary for their production.

§ 20. In § 13 of my first communication it was stated that X-rays not only originate in glass, but also in aluminium. Continuing my researches in this direction I have found no solid bodies incapable of generating X-rays under the influence of cathode rays. I know of no reason why liquids and gases should not behave in the same way.

Quantitative differences in the behaviour of different bodies have, however, revealed themselves. If, for example, we let the cathode rays fall on a plate, one half consisting of a 0·3mm. sheet of platinum and the other half of 1mm. sheet of aluminium, a pin-hole photograph of this double plate will show that the sheet of platinum emits a far greater number of X-rays than does the aluminium sheet, this remark applying in either case to the side upon which the cathode rays impinge. From the reverse side of the platinum, however, practically no X-rays are emitted, but from the reverse side of the aluminium a relatively large number are radiated. It is easy to construct an explanation of this observation, still it is to be recommended that before so doing we should learn a little more about the characteristics of X-rays.

It must be mentioned, however, that this fact has a practical bearing. Judging by my experiments up to now, platinum is the best for generating the most powerful X-rays. I used a few weeks ago, with excellent results, a discharge apparatus in which a concave mirror of aluminium acted as cathode and a sheet of platinum as anode, the platinum being at an angle of 45deg. to the axis of the mirror and at the centre of curvature.

§ 21. The X-rays in this apparatus start from the anode. I conclude from experiments with variously-shaped apparatus that as regards the intensity of the X-rays it is a matter of indifference whether or no the spot at which these rays are generated be the anode. With a special view to researches with alternate-currents from a Tesla transformer, a discharge-apparatus is being made in which both electrodes are concave aluminium mirrors, their axes being at right angles; at the common centre of curvature there is a "cathode-ray catching" sheet of platinum. As to the utility of this apparatus I will report further at a later date.

DISCHARGE PHENOMENA IN RAREFIED METALLIC VAPOURS.*

BY E. WIEDEMANN AND G. C. SCHMIDT.

While the phenomena occurring at the anode and cathode, and in the positive light column in a discharge tube (stratification, dark space, glow light, cathode rays), have been variously investigated for permanent gases, this has hardly yet been done as regards metallic vapours.†

And yet such experiments promise many interesting disclosures. For many metals it has been proved by their vapour densities that their molecules are monatomic. Changes in the spectra of such a metallic vapour are not therefore to be generally explained by the splitting up of the molecules into atoms, but by the different temperatures of the luminous particles, or by different kinds of excitation. It is only under well-determined conditions that we must contemplate the combination of several atoms to large molecules, such as liquidogenic molecules in de Heen's sense.

Arrangement.

The metallic vapours were contained in exhausted glass bulbs, fusible with more or less difficulty according to circumstances. Small portions of the metal were thrown into the bulb, its neck was drawn out, and a piece of soft glass fused in to connect with the pump. The metal was introduced into the neck and the bulb heated during exhaustion to expel moisture and hydrocarbons. Electric discharge was produced in the bulbs by means of two rings R and R^1 (Fig. 1) covered with wire netting about 6cm. in diameter. These were either connected directly with the two terminals of an influence machine kept 2mm. to 3mm. apart, or they formed the terminal condensers of a Lecher wire system. The wire nets were fastened on slides, and could be approached to the bulb or withdrawn from it. The bulb was heated by a flame between the wire nets.

Course of the Phenomena during Direct Connection with the Machine.

If the rings are put into contact with the cold glass bulb, sparks pass, in the first place, between the terminals of the machine.

* *Wied. Ann.* 57, pp. 454-458, 1896.

† A few experiments upon mercury are described by Schuster, *Proc. Roy. Soc.*, 37, p. 318, 1884. E. Warburg, *Wied. Ann.*, 40, p. 12, 1890.

Digitized by Google

This discharge of the machine prevents the penetration of the bulb before the conductivity of the glass has been brought by heating to such a point that electricity can be continuously conveyed to the metallic vapour. As the temperature is raised still further, the discharge takes place steadily through the conducting glass. But as soon as the rings R are withdrawn a little from the glass walls, so that sparks pass from the rings on to the glass, the gas flashes out and shows all the characteristic phenomena of discharge (with suitable sparking distances and pressures): first cathode stratum, Goldstein's dark cathode space (second stratum), glow discharge (third stratum), dark separation space, and positive light column. With decreasing temperature, and consequently decreasing pressure, or with a constant temperature and increasing exhaustion, the usually observed phenomena also occur in the case of metallic vapours—increase of thickness of the dark space, stronger development of the glow stratum, recession of the positive light.

The phenomena observed at suitable pressure are shown in Fig. 2. k is the first stratum, more or less developed; g is the glow light. The portion g_1 towards the cathode is often of a different colour from the portion g_2 towards the anode. d is the dark separation space, and p the positive light sheaf, which in many cases appears beautifully stratified. In almost every case the domes of the strata have a different colour from the posterior portions.

That in these experiments we observe in the gas, surrounded as it is by a conducting glass sheet, a passage of electricity and a glow, is consistent with the general behaviour of gases and ordinary conductors under the influence of oscillations.

If the metallic nets immediately adjoin the strongly-heated bulb, a practically constant current passes through the glass walls. On withdrawing the nets a little from the glass, small sparks pass over to it, *i.e.*, an oscillating discharge takes place and passes through the conducting glass to the metallic vapours in the interior and makes the gas glow, or excites the molecules, so that they can glow with absorption of electric energy. As far as other experiments go, when spark-gaps are in circuit, the normal discharge

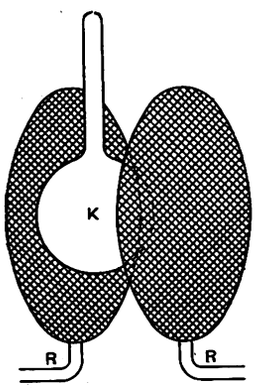

FIG. 1.

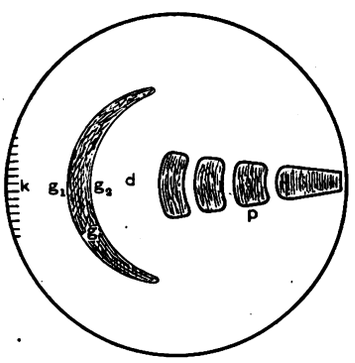

FIG. 2.

phenomena are replaced by irregular confused ones. If all the same the typical appearance is often beautifully presented, this is due to the fact that in consequence of the high resistance of the glass the passage of the electricity to the excited gas takes place so slowly that we can obtain normal discharges.*

The fact that a gas enclosed in the interior of a conductor may be made to glow by means of oscillations, is made possible in any case where the above arrangement is adopted.

In a few cases we used the two-wire net plates as terminals of a bridged Lecher wire system, thus exposing the metallic vapours to the influence of regular slightly damped oscillations; as in all other gases the cathode phenomena appear on *both* sides, and the positive light in the centre.†

We shall now describe the phenomena in detail only for those metals with whom they may be easily obtained, and which show characteristic colourings. Small changes in the colour occur when the quantity of the vapour is changed by different heating. In the main we have the following results:—

Sodium, k orange, g whitish, p yellow.

Potassium, k, &c., whitish, p purple.

Magnesium, all intensely green.

Thallium, k, &c., light blue, p green.

Cadmium, k greenish-blue to violet, g_1 pink, g_2 violet, p green on the whole, the domes green, the further portions violet. The positive light shows the smallest number of lines, next the first cathode stratum, and the glow light the largest number.

Zinc, k blue, g_1 reddish, g_2 purple, p reddish, the domes violet, the posterior portions reddish. The glow light shows most lines.

In zinc and cadmium the colours are very brilliant.

Mercury, differences between anode and cathode are small; in the spectrum of the positive light there is a continuous band in the green already observed by Warburg.

Arsenic, k whitish, g bluish, p green.

Tellurium, everything bluish.

In a number of the monatomic metals among those mentioned, the typical differences between anode and cathode phenomena appear very distinctly. In ordinary discharge tubes with fused-in electrodes A. Schuster has not succeed in observing those with the monatomic mercury. But even in this case difference in the appearance and in the spectrum occurs, as we, and also Warburg, were able to establish some time ago. But they are not very striking, since the colour of the light is nearly uniform.

Summary.

1. In a heated conducting glass bulb, rarefied metallic vapours may be made to glow by oscillating discharges.
2. In metallic vapours the typical discharge phenomena occur, even in monatomic ones. Colour and spectrum of the first and third glow-light strata and of the positive light are essentially different.

EUROPEAN ELECTRIC TRAMWAY STATISTICS.

In its issue for March 10th *l'Industrie Electrique* gives as a supplement a very comprehensive statistical table relating to European electric tramways in operation, in construction, and projected on January 1, 1896. During 1895 the number of lines in operation have increased from 70 to 111, their total length having increased from 700 to 902 kilometres, the total capacity of the power stations in kilowatts has increased from 18,150 to 25,095, and the number of motor cars from 1,237 to 1,747. Germany continues to head the list with 406 kilometres of line, France coming second with 132 kilometres, and the United Kingdom third with 109 kilometres. The overhead conductor system continues to hold its own, being employed on 91 lines, whilst there are only three underground conductor lines and nine central rail lines, eight of which are in the United Kingdom. The total of 111 lines is completed by eight accumulator systems. Below we give a summary of our contemporary's valuable table, which, it will be observed, somewhat anticipates events in the matter of the sister isle:—

Countries.	Kilometres of line.	Power in kilowatts.	Motor cars.
Germany	406·4	7,194	857
England	94·3	4,243	143
Austro-Hungry	71·0	1,949	157
Belgium	25·0	1,120	48
Bosnia	5·6	75	6
Spain	29·0	600	26
France	132 0	4,490	225
Holland	3·2	320	14
Ireland	13·0	440	25
Italy	39·7	1,890	84
Scandinavia	7·5	225	15
Portugal	2·8	110	3
Roumania	5·5	140	15
Russia	10·0	540	32
Servia	10·0	200	11
Switzerland	47·0	1,559	86
Totals	902·0	25,095	1,747

Countries.	Overhead conductor lines.	Conduit lines.	Central rail lines.	Accumulator lines.	Total.

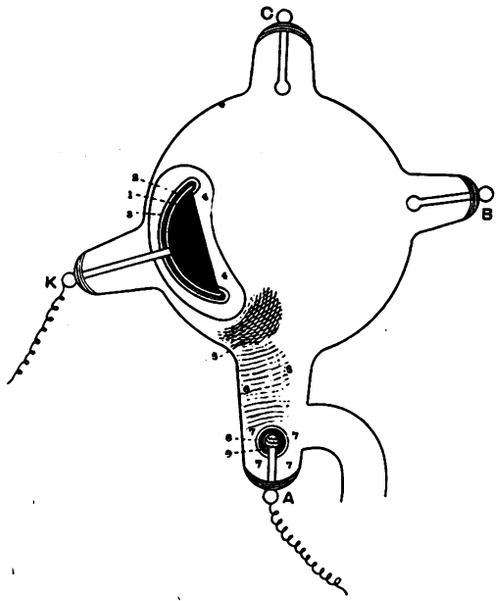
ON A CROOKES APPARATUS.*

BY H. PFLAUM.

To show the difference between the discharges in a moderately and highly exhausted space respectively, Crookes† used two glass bulbs designated by No. 7A and 7B, which were perfectly equal in shape and only differed in degree of exhaustion. While in the first bulb the air had a pressure of several millimetres, it was extremely rarefied in the second. (By Crookes it was said to be exhausted to a millionth of an atmosphere). Three point electrodes A, B, C, and another K, in the form of a concave mirror, were fused in. If, in the bulb 7A, A, B, and C were made the anode in succession, K remaining the cathode, a violet light stream went from the cathode to the anode for the time being. If the same experiment was repeated with apparatus 7B, another phenomenon took place, which was the same whether A, B, or C was the anode. From the concave mirror a beam converged to the centre of curvature of the mirror, diverged from this, and produced vivid fluorescence on the glass wall.

When at the beginning of this year I had an occasion to experiment with apparatus constructed in 1880 for this Polytechnikum, by Leybold, in Cologne, in accordance with Crookes's indications, I observed the same effects again. These bulbs were exhibited at the Physical Exhibition held at Riga in that year. They worked satisfactorily in spite of frequent use by the public. But when I tested the apparatus a few weeks after the exhibition, I found that 7B had become useless. I therefore ordered new specimens of 7A and 7B of the scientific mechanician, F. Ernecke, in Berlin. The bulb 7A did show the phenomenon described; but 7B showed a behaviour differing to such an extent that I feel impelled to publish a description of it.



If K is made the cathode, and A, B or C the anode, a yellowish-grey stratified light extends from the anode to the cathode, while the hollow cathode is completely enveloped in a bluish-white glow. This much is seen with a cursory glance, that the position of the anode is not without influence upon the shape of the light effect. Besides, the green fluorescence of the glass on the plates opposite the cathode is not more intense than at all the other places where it occurs, *e.g.*, behind the cathode, between A and K, or between C and K. The phenomenon in question is quite different from that observed in the moderately exhausted bulb.‡

On close inspection the following details are discernible (*see* Fig. 1). A halo of white light (1), about 0·8mm. thick, immediately surrounds the cathode, at the back of which it is very plainly seen. Then follows a darker layer of the same thickness (2). This is succeeded by a bright white layer (3), 1mm. to 1½mm. thick, and this by a fainter light (4), which continually becomes fainter. It may be traced as far as the wall of the vessel behind the cathode (towards the left in the figure), while in front of the cathode it gets steadily dimmer, and extends to about a centimetre from the surface. Towards the anode this glow is followed by a very dark space (5), evidently the "separation space" (Wiedemann), and this is succeeded by a series of 12 to 15 cloudy striæ of various thicknesses and intervals, concave towards the anode, of a yellowish-grey colour, and vibrating rapidly.* The striæ are bounded on both sides by a very faint violet glow. The striæ towards the anode appear crowded so close together that they appear to pass almost imperceptibly into a faint grey stationary glow, which extends behind the point anode (7). Within this glow lies the anode, surrounded by a brighter layer (8), succeeded by a darker one (9). Just round the anode lies a very bright white halo, the light of which appears disturbed again, as if flickering. If, instead of A, the electrodes B or C are made the anodes, the layers are directed towards B or C. Otherwise the discharge remains the same.

I should also mention the phenomenon observed when K is made the anode, and, say, A the cathode. The concave anode is then, as was the cathode, surrounded by a luminous glow, in which we may distinguish the same parts (*see* Figure, 1—4). But the dark separation space is now succeeded by continuous light, which becomes steadily brighter towards the cathode. The point cathode has now the same appearance as the point anode had in the first experiment, viz., the flickering halo is surrounded by a dark and this by a light space. Stratifications are nowhere to be seen. The fluorescence of the glass remains the same as before. Now and again a small spark bursts from the cathode, accompanied by a momentary brightening of the glow between cathode and separation space. Photographs of the bulbs show less than is seen with the naked eye, and ultra-violet light, which might be expected to play a part in the phenomenon, does not appear on any of the negatives.

Riga, October, 1895.

* *Wied. Ann.*, No. 3, 1896, p. 443.

† *Radiant Matter.*

‡ The conditions of the experiment were the following:—A storage battery of eight cells gave the primary current of 3·9 to 4·6 amperes; the induction current was furnished by a large induction coil with platinum interruptor (74mm. sparking distance). The observations were made in a perfectly obscured place, so as to perceive even the most delicate light details.

* Their situation, distance and number depends upon the strength of the induction current. As the current increases they are drawn towards the cathode, as it diminishes they recede towards the anode.

PUBLIC LIGHTING BY ARC LAMPS.†

BY ANDRÉ BLONDEL.

(*Continued from page* 823.)

Dioptric Methods.

In using dioptric methods we may set ourselves two distinct objects to be attained, corresponding to the two *desiderata* of lighting:—1st. The reduction of the losses of light generally accompanying diffusion. 2nd. The distribution of the light in the most advantageous manner without sacrificing diffusion.

A certain number of inventors have sought to attain one or other, or even both, of these objects, with varying success. They have had recourse to the well-known properties of refraction and reflection, which they have employed each with its own particular object.

Dioptric Diffusion.—The principle of this method consists in covering a globe of transparent glass with a network of small refracting elements, each producing a divergence or expansion of of the rays received by it. The first attempts in this direction were made with ribbed glass, the origin of which is very ancient, and difficult to ascertain. Plain ribs produced a certain amount of spreading of the light in a direction perpendicular to the genatrices of the ribs. Glass of this kind has recently been adopted for the lanterns in the city of London. According to Mr. Preece, they entail a loss of only 21 per cent., but they are very bad from the point of view of diffusion, on which point, however, not much trouble appears to have been taken. Similar glass panes, with horizontal ribs, have been used in lighting the stations of the Midland Railway. They have the advantage of preventing shadows, even at the foot of the pillars. When using globes of this nature Mr. Raffard (in 1881) had the idea, recently taken up again,[39] of placing two such panes with their ribs at right angles to each other, so as to obtain diffusion in both directions. A much better diffusion is obtained with lanterns so fitted than with those fitted in the usual way, though the result is still not perfect. In 1883 Mr. A. P. Trotter,[40] one of the best-versed engineers in photometric questions, attained the same result in a much easier manner by the aid of single glasses, arranging two series of ribs, one on each side of the glass, each rib having an almost circular section.[41] With this arrangement diffusion was still imperfect, and the losses of light considerable, from reasons indicated later.

Dioptric Distribution of Light.—The idea of distributing light according to a given law by the use of refracting rings was first suggested by Fresnel fifty years ago, since which time many similar attempts have been made. But instead of being cut out

† From *La Révue Technique.* Translated by Mr. John Hesketh.

[40] *Proc.* Inst. C.E., 1883.

[41] The arrangement of orthogonal flutings on the same glass seems to have been first pointed out by Messrs. Cooper and Richardson (1870), but without any explanation or theory.

Digitized by Google

separately and then fastened together—a very expensive system, which was at first employed—these rings may be made in the form of horizontal grooves or steps on either lantern panes or globes.[42] The profile of these steps or *échelons* is easily determined. In Fig. 39 let P N be the internal shape of the glass which is placed in a predetermined position relative to O, the source of light. The external shape, M *a* N, is determined algebraically or geometrically by the condition that the incident rays of the source O shall be refracted in different directions, so that the illumination on the ground is uniform. The solution of this elementary problem was,

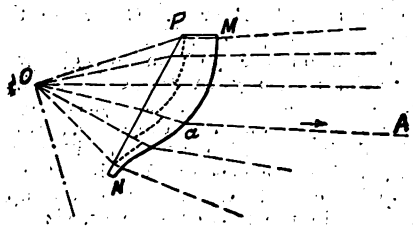

Fig. 39.—Principle of Lenses in *échelon* applied to the Distribution of Light.

I think, given by M. Weissenbruch in 1889. In practice the glass would be too thick if it were made in one continuous section. It may then be divided into several parts, which are afterwards fitted together. In this manner a series of lenses is built up which differs from those in use in lighthouses only in that the rays instead of being emitted parallel, form a diverging cone. But to obtain any desired distribution, account must be taken of the intensity of the incident light in each direction; this naturally changes with the source of light employed. Besides, in the vertical direction,

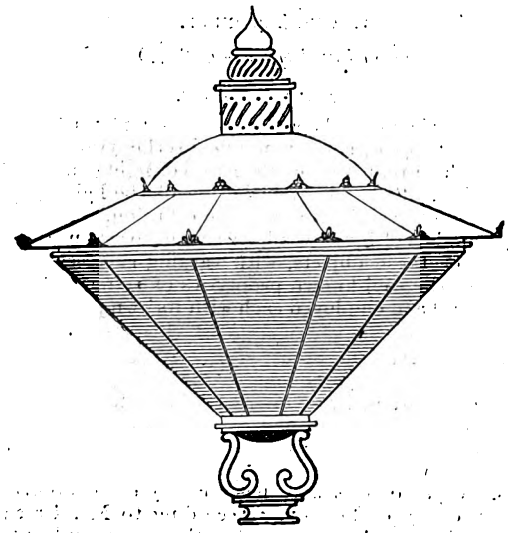

Fig. 40.—Trotter Polygonal Lantern with Reflector and Ribbed Glass.

distribution but not diffusion is obtained, because each rib only sends light out in a single direction, so that an observer at A (Fig. 39) only perceives one groove *a* as luminous, and this one naturally appears dazzling. In addition, these globes absorb a considerable portion of the light by reflection, as will be mentioned later. Mr. Trotter, who in 1883 employed such a system* in the manner shown in Fig. 40, succeeded in minimising its inconveniences

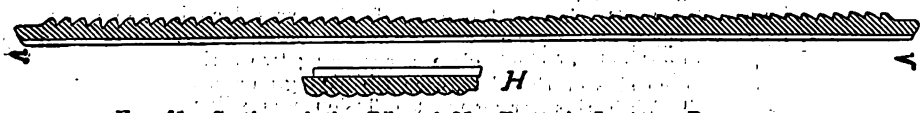

Fig. 41.—Section of the Ribs of Mr. Trotter's Lantern Panes. V. Vertical Section. H. Horizontal Section.

by adding interior ribs to give a certain horizontal spreading of the rays, and giving the purely refracting exterior ribs a profile which rendered them capable of partially diffusing the light. The profiles

* Fig. 39 is taken from Mr. A. P. Trotter's patent. For the description of his system, see his able Paper "On the Uniform Distribution of Light."

[42] This arrangement was first applied to lighthouses by M. Degrand, but owing to the result obtained not being sufficiently accurate it was not successful. The same writer also published a complete set of fittings for public lighting (English patent, 1857), but does not appear to have even carried out his ingenious inventions.

he used are shown in Fig. 41. The ribbed panes are confined to an inverted cone of 45deg.; they receive the light at any angle varying from 15deg. to 90deg. from the vertical, and send it out at an angle of 74deg. The essential end Mr. Trotter had in view was

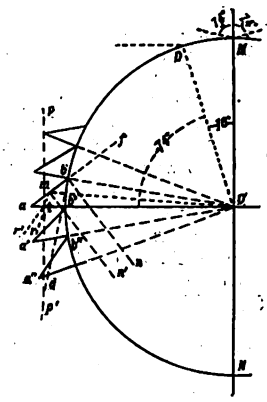

Fig. 42.—Frédureau System of Diffusing Rings.

to obtain uniform horizontal illumination in a circle of a diameter of seven times the height of the lamp; and to this he very closely approximated by calculating most carefully the section of the diffusing glass. The lantern was completed by a silvered

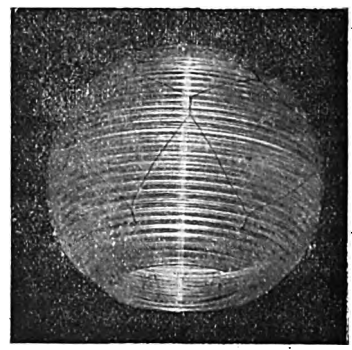

Fig. 43.—Effect produced by Frédureau Diffusing Globe, with 10 ampere Continuous-current Arc.

reflector, which directed all the light emitted above the horizontal on to the cut glass. Owing to its high price this ingenious device did not meet with the success it deserved; its shape and various technical defects, especially the employment of purely refracting

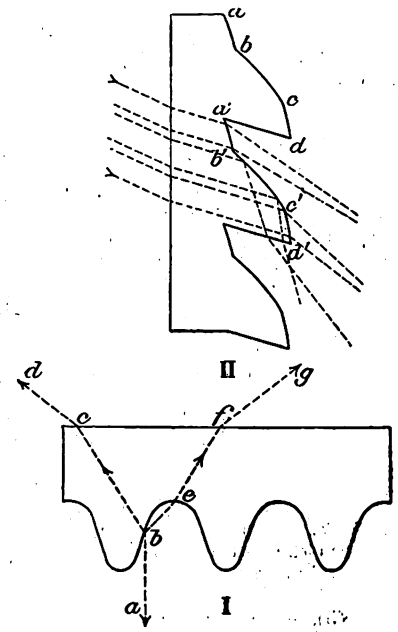

Fig. 44.—I. Average Profile of the Internal Ribs of a Holophane Globe for Public Lighting. II. Typical Combined Reflecting and Refracting External Ribs of the same Globe.

grooves, which do not lend themselves to practical use, and only allow of sufficient diffusion at the risk of losing much light by internal reflection, also militated against it. More recently, M.

Digitized by Google

Frédureau reverted to the old system of M. Degrand, and renouncing double ribbing, has constructed globes with simple prismatic or parabolic external zones, simply to reflect as much of the light downwards as possible. Such a globe is shown in Fig. 42. This figure, which is reproduced from *l'Electricien*, shows that each of the steps acts by total reflection like a catadioptric ring, and thus sends a large proportion of the light towards the ground. No particulars as to the results obtained with this kind of globe are at our disposal, so we are unable to say how efficient it would prove for public lighting. The fact that these globes produce a distribution

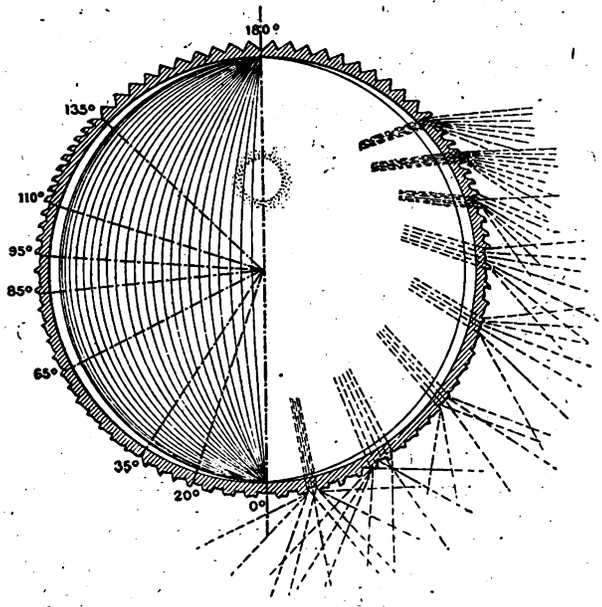

FIG. 45.—Vertical Section of Holophane Globe.

and not a diffusion of the light, is shown by the photograph, Fig. 43. Owing to the excessive internal reflection to which these globes give rise, it will readily be seen that a considerable loss of light results.

Holophane Globes.—This again is a globe with the double ribs used in many of the preceding examples, but with certain special differences. The external ribs differ from all the preceding forms in their profile; each rib is a combination of two independent sec-

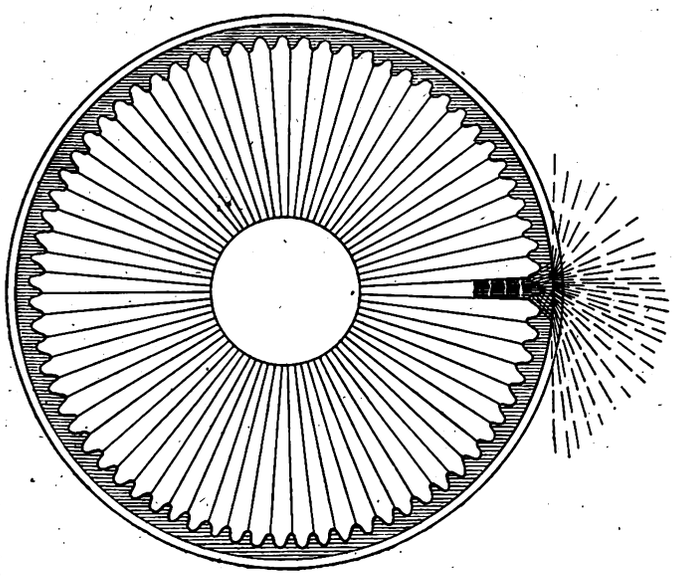

FIG. 46.—Horizontal (centre) Section of Holophane Globe.

tions, one *refracting*, the other *reflecting*, arranged so as to suppress all acute angles, as shown in Fig. 44 II. With this combination a very good diffusion of light can be obtained over a considerable angle without any appreciable loss; the globes themselves appear to be luminous all over, as shown in Fig. 49, and it is on this account that the inventors have given them the name of *holophane* (ολος, entirely; φαινω, to shine). This great diffusion, which the spherical shape of the globe rendered it particularly difficult to attain, makes the globes look as soft as opal globes,[43] and the physiological desideratum is thus satisfied. Moreover, this result is not arrived at in an arbitrary fashion, but by means of calculations too long to be given here, and according to the law of distribu-

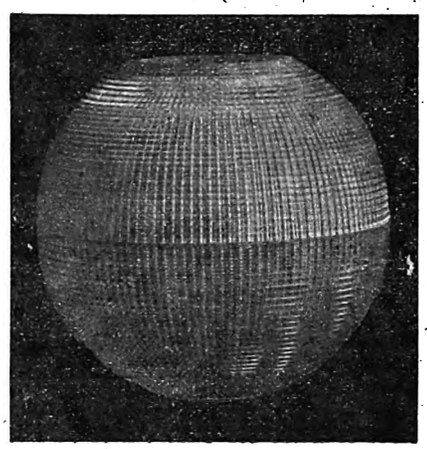

FIG. 47.—View of External Parallel Ribs of Holophane Globe.

tion which seems the most advantageous in each case.[44] The type of holophane globe used for public lighting is 34cm. diameter, so as to fit lamps at present in use. The arc is fixed 10cm. above

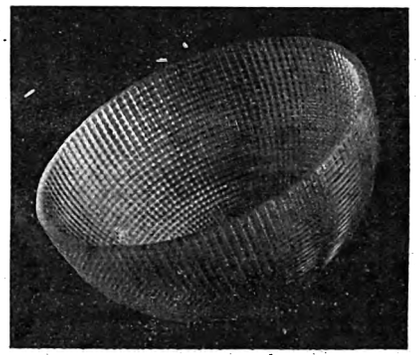

FIG. 48.—View of Internal Ribs of Holophane Globe.

the centre as usual. Figs. 47 and 48 show the external and internal ribs or channels, of which Figs. 45 and 46 are sections. These ribs have been calculated to give definite effects. The average profile

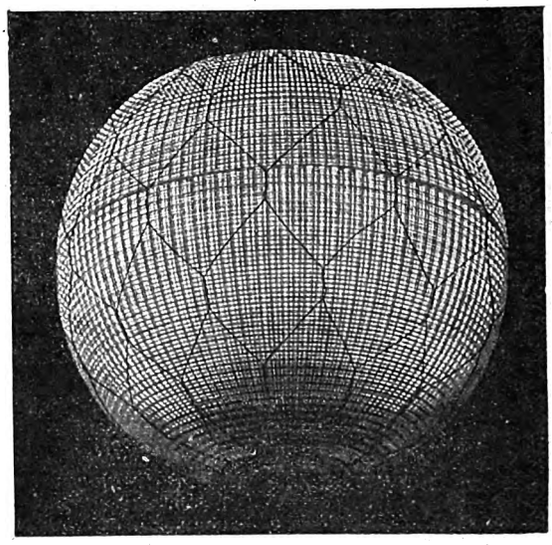

FIG. 49.—Effect produced by Holophane Globe with 10-ampere Continuous-current Arc.

of the internal ribs (Fig. 44 I.) is intended to ensure horizontal diffusion according to the law of cosines; and the external

[43] In reality the luminous surface is formed by an infinite number of small images of the arc, so weak and so close together that the eye completely mixes them up.

[44] Further details will be found in an interesting article in *L'Industrie Électrique* of October 10, 1894, written by M. Claude.

Digitized by Google

ribs (Fig. 44 II.) are calculated according to the law decided on for vertical distribution. Fig. 45 shows the result obtained, which result is, moreover, to a certain extent independent of the source of light employed. The law of distribution was discussed in my former article (see *The Electrician*, Vol. XXXVI., November 1, 1895, *et seq.*), and some experimental results are given later. The ribs at the upper portion of the globe are specially designed so as to totally reflect the rays towards the centre of the globe, and yet in such a way as to just escape the carbons. This system of double ribs may be used for almost any system of non-deteriorating reflectors.

(To be continued.)

THE FOUNDATIONS OF THE NEW 1,000-KILOWATT ALTERNATOR AND ENGINE AT DEPTFORD.*

BY J. HETHERINGTON.

A potent factor in the comfortable running of high-speed machinery lies in a massive and trustworthy foundation to which the plant can be securely anchored. Where directly-coupled engines and machines are of such construction and dimensions as to preclude an iron bed-plate, common to the whole, the foundation to which the separate items are fixed has to be answerable for the permanent alignment and consequent smooth running, which would otherwise have been attained by a cast-iron sub-structure, making practically one machine of the driver and driven parts. The foundation, in this respect, being made an integral part of the machinery, its construction, stability and quality are of first-class importance.

An installation in which the above conditions were to be observed was last autumn put into commission in the Deptford generating station of the London Electric Supply Corporation. This station is famous for many unique mechanical and electrical combinations, and the latest unit possesses many interesting peculiarities, which have been fully chronicled in the technical periodicals.

As affecting the question of foundations, there is an engine, some 70 or 80 tons in weight, driving a three-throw crank shaft coupled directly to the shaft of the armature by a rigid coupling. This shaft is over 12ft. long, and carries a revolving armature nearly 40 tons in weight. The field magnet frames for this require a pit 22ft. long, 6ft. wide, and 11ft. deep, and add about 40 tons more. One bearing of this machine is pinned and bolted to the bed-plate of the engine, while the other is aligned with, and connected to, it only by the concrete foundation.

The speed at which the plant is run gives a circumferential speed to the armature bobbins of over 10,000ft. per minute, or nearly two miles. Such weights, moving at this velocity, require, for satisfactory working, perfectly linable bearings, which imply a foundation that will, once the bearings are right, keep them permanently so without vibration or other undesirable movement. Accordingly, unusual care was bestowed on the formation of the concrete block to which the above plant is bolted, with results satisfactory not only to the contractors for the dynamo and engines, but also to the corporation's engineer-in-chief, Mr. P. W. D'Alton, M.I.M.E., under whose directions the foundation was put in by the corporation's own workmen.

The site for the block is on a previously laid concrete floor, planned for 10,000 H.P. direct-driven dynamos (since abandoned), and at a level too low for the general purposes of the station, as well as for the sinking of a pit for the dynamo. On this account the foundation of the new unit is nearly wholly above the floor, being raised 10ft., and is in itself an interesting bit of engineering work.

The first consideration in making the block was a thoroughly efficient bond to the existing concrete floor, which is above 5ft. thick. A clean, fresh surface was obtained by taking off a layer, 1ft. thick, over the whole area to be occupied by the new work, while by slightly undercutting the margin, a dovetail was produced for keying the new work to the old.

A wooden mould, of the shape of the block, was made of 1in. boards, nailed to battens, with vertical timbers 6in. square, at every corner and midway of the long sides. Horizontal timbers of the same section were spiked to the top of these, so as to tie the cross part of the T to the upright part, the plan being in the shape of a hugh letter T, with the engine on the shank and the flywheel armature on the cross. Cross timbers of the same size were fixed on the tops of these to tie in the sides, and on the upper side of these the tipping floor was laid, commanding the whole space below.

On the under side of the cross timbers were arranged supports to take the tops of the bolt cores, so fitted that their accuracy could be checked as often as desired by reference to fixed points outside and altogether independent of the framing itself, and compensation could be easily made for any distortion caused by the dry wood absorbing moisture from the concrete.

Between these points fine lines were stretched, passing through ½in. holes in the pieces A (Fig. 1), a saw cut from the holes to the lower ends of the pieces allowing them to be put on over the strings. Battens 1½in. thick, fixed to the bottoms of these pieces, were bored at the proper places, as determined by the lines, and the bolt cores trimmed to fit the holes at one end and the plates at the lower end. This arrangement being lined so that the strings were in the centre of the holes in the pieces A, any movement could be at once detected and allowed for by the wood-screws above. Only ½in. on each side of the holding-down bolts was allowed in the concrete for grouting in when the engine and dynamo were correctly placed and levelled, and every one of the 42 holes was found to be accurately under the corresponding holes in the bed-plate and bearing blocks. Portland cement of the very best quality was used in making the concrete, finely ground and

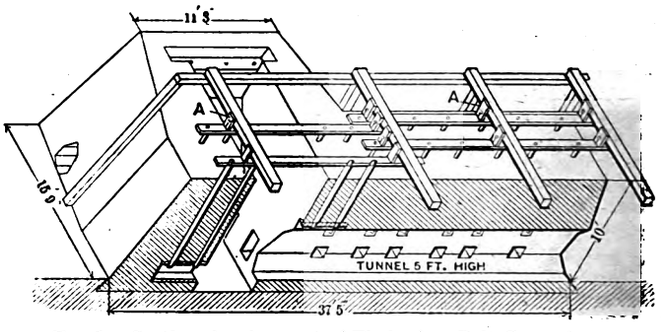

FIG. 1.—Section showing part of Timbering, Bolt Cores, &c.

weighing over 115lb. per striked bushel (1·28 cubic ft.) after quietly filling the measure, and with a tensile strength of 300lb. per square inch after seven days' immersion. It was thoroughly cooled before being used.

The ballast was specially selected from dredgings from the river Thames, and was remarkable for its freedom from any impurities detrimental to the proper binding of the mortar with the aggregate. As brought up it contained too large a proportion of sharp sand, and the whole of it was screened, leaving a heap composed of particles of every size from sand up to flints from 6in. to 8in. long. After careful tests to determine the interstitial space, the sand being somewhat coarse, the following proportions were used:—

Ballast.....	36 cubic feet
Sand	7½ ,,
Cement	6 ,,

This is equivalent to 7¼ to 1, or practically six parts of aggregate to one of matrix. About one-fifth of the total bulk of dredged

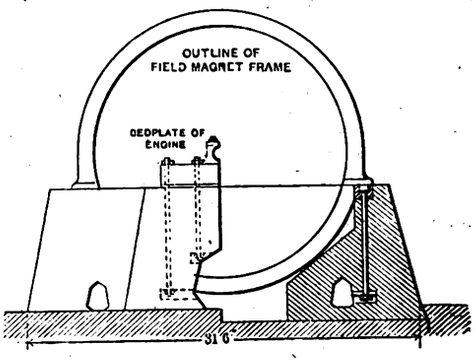

FIG. 2.—End View and Section through Armature Race.

material was left over as surplus sand, in excess of what was required. This was quickly disposed of to builders at current rates. The concrete was turned twice dry and twice wet and was necessarily dropped into the foundation from a considerable height at the beginning, gradually diminished as the work rose in the frame.

As the area to be gone over was very large, the starting point got fairly set before the men worked round to it again with a layer 18in. thick each round, and in order to check the too rapid evaporation of moisture by the hot dry air of the engine room, water was sprayed over the surface of the layers at intervals from a hose pipe laid on for the purpose. Tunnels were moulded in the block to give access to the lower ends of the foundation bolts which connect to cast-iron plates worked in as the concrete rose, and to provide an entrance to the armature race. The total quantity of

* Abstract from *Cassier's Magazine*. For a description of the engine and alternator see *The Electrician*, November 29, 1895, p. 147.

Digitized by Google

concrete in the block is 230 cubic yards, weighing about 390 tons, of which close upon 50 tons are cement.

Apprehension was felt that cracks would develop in the work as it hardened, due to the shrinkage of cement, and experienced concrete engineers had predicted that the finished block would not be a monolith. These fears have so far proved groundless, and the most careful examination at the points of weakest section, and where contraction strains were most likely to accumulate, fails to reveal even a hair-wide crack, although the machinery has been daily running for some months. To all appearance the block is as solid as if hewn in rock.

ON THE EFFECT OF THE RÖNTGEN X-RAYS ON THE CONTACT ELECTRICITY OF METALS.*

BY JAMES R. ERSKINE MURRAY.

The experiments described in this communication were made in the Cavendish Laboratory of the University of Cambridge, at Prof. J. J. Thomson's suggestion, in order to find whether the contact potential of a pair of plates of different metals is in any way affected by the passage of the Röntgen X-rays between the plates.

The vacuum bulb and induction coil for the production of the rays were enclosed in a box lined with metal, so that the plates and the apparatus used in measuring their contact potential difference should be screened from any direct electrical disturbances. To measure the contact potential the null method described by Lord Kelvin in his Paper given to the British Association in 1880 was used. The plates were of zinc and tinfoil, the latter being mounted on thin ebonite to keep it flat. They were placed parallel to one another at a small distance apart, so that the rays fell perpendicularly on the back of the tinfoil plate, passed through it and the air space between them, and were absorbed by the zinc. The tinfoil plate was insulated and connected to insulated quadrants of a Kelvin quadrant electrometer. The zinc was uninsulated, and was connected to the uninsulated quadrants of the electrometer. This plate was movable in a direction perpendicular to its plane, and could thus be drawn away from the tinfoil.

Before the rays were turned on, the contact potential of the plates was measured and found to be +0·44 volt, the zinc being positive to the tinfoil. The rays were now turned on. The contact potential, measured while the rays were passing, was about +0·43 volt. But before the plates could be separated to see whether the counter potential applied had annulled the contact potential or not, the charge leaked away as if the insulation of the tinfoil plate were bad. It was also observed that when the plates were not in connection with one another, but only with the electrometer, they seemed to act as though they were connected together by a bad conductor or an electrolyte.

The X-rays were now turned on so as to pass perpendicularly through the tinfoil plate on to the zinc. In a few minutes the deflection indicated −0·50 volt, and remained steady there for several minutes. While in this condition the plates were separated. The deflection increased by a small amount, showing that the electrolytic power of the air while the rays were passing through it had somewhat more than counterbalanced the contact potential of the plates, and had established a slight difference of potential in the direction opposite to that which exists between the surfaces of the plates when connected metallically in air. This was confirmed by a measurement, made immediately after, which gave +0·44 volt for the potential difference between the plates; the rays not being on at the time.

In the experiments described above, the rays had fallen perpendicularly on the plates, passing through the tinfoil. The plates were now placed so that the rays should pass between them in a direction approximately parallel to their surfaces. On breaking the metallic connection between the plates and turning on the rays the electrometer rose to −0·39 volt, and remained steady there. Separating the plates produced no further deflection, which shows that the contact potential difference between the surfaces of the plates has been reduced to zero. This was confirmed by the measurement, made by the null method, of their contact potential, which was now +0·39 volt.

In the above experiment the plates were at about one centimetre apart. The distance between them was now increased to two, then to five, and then to 10 centimetres; but in spite of the fact in the last case the rays must have passed almost entirely through the air between the plates without striking on their surfaces, the electrometer always crept up from zero to −0·39 volt in a minute or two, and remained almost steady at that value.

In order to find whether these phenomena were strictly comparable with the results which Lord Kelvin had got many years ago by connecting the plates through an electrolyte, several experiments were made in which connection was made by a drop of acidulated water. Before doing so, their potential difference was found to be +0·57 volt. Joining the plates by a drop of acidulated water while they were in connection with the electrometer only, the deflection at once rose from zero to −0·54 volt. After a short while the deflection fell to −0·48 volt, which was nearly the value found previously for untarnished zinc and tinfoil in air, showing that the acidulated water had in all probability removed the tarnish, and was now balancing the contact potential between clean surfaces of the metals. The water was now removed, and the contact potential measured by the null method as before. It was still +0·57 volt, for, of course, by far the greater part of the surfaces of the plates was still tarnished as before.

It now occurred to the author that perhaps the electrolytic connection established between the plates when the rays were passing might be through the insulating supports of the tinfoil plate, and not through the air, as hitherto supposed. To test the truth of this idea, several variations were made in the arrangements, all with a view to place the insulators in such a position that the rays could not reach them. When the rays were started the electrometer moved from zero to a position which indicated a difference of potential as great as or greater than any which had been previously observed. This showed that the electrolytic connection had not been at all affected by screening the solid insulators.

The author has observed that the activity of the vacuum bulb seems to determine to some extent the potential difference observed on the electrometer. The conclusions the author draws from these experiments are that (1) the influence of the rays on the zinc and tinfoil plates does not cause any direct or sudden change in their contact potential, but that (2) the air through which the rays pass is temporarily converted into an electrolyte, and when in this condition forms a connection between the plates which has the same properties as a drop of acidulated water, namely, it rapidly reduces the potential between the opposing surfaces of the plates to zero, and may even reverse it to a small extent.

It is interesting to note that this electrolytic property was found by Lord Kelvin ("Electrostatics and Magnetism," Art. XXIII, §§ 412—414) to be possessed by the fumes from a burning spirit lamp. In both cases its cause is probably the same. It is, no doubt, due to a want of electrical equilibrium among and a partial dissociation of the molecules of the gas.

SPECIAL NOTICE.

The present number of "The Electrician" completes Volume XXXVI. With next week's number will be issued (Gratis) the Index to the Volume.

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d. post free 13s. 6d. Many of these Volumes are very scarce.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

In a few weeks' time the present stormy and somewhat unsatisfactory session of the Institution of Electrical Engineers will come to an end, and, so far as the average member or associate is concerned, the very existence of the Institution will be temporarily forgotten. To the devotees of *laisser-faire* this is a consummation devoutly to be wished. There is, indeed, a time for all things, even for a policy of procrastination; but we cannot help thinking that the Council of the Institution will be ill-advised in postponing the much-needed emendation of the Articles of Association until after the recess or, as some no doubt wish, until the Greek Kalends. The long-existing feeling of dissatisfaction with the management of the affairs of the Institution has culminated within the past six months in a succession of disagreeable incidents. First of all, the Presidency became a subject of considerable agitation and discussion, and an open battle was only narrowly avoided. Then, at the annual general meeting "held at meeting next previous to Christmas Eve," a determined but unsuccessful attempt was made to secure the appointment of a committee to consult with the Council on matters affecting the welfare of the Institution. Lastly, at a recent meeting, the balance sheet was referred back for amendment. It needs but the most elementary acquaintance with the art of diagnosis to argue from these symptoms that something is rotten in the state of Denmark, and the allegation is that the Council, owing to the slow influx of fresh blood and the dead-weight of the votes of 13 or 14 Past-Presidents, is out of touch with

CLASSIFIED TRADES' INDEX to ADVERTISERS in "THE ELECTRICIAN."

The following forms a List of the Leading Firms in the Electrical and Engineering Trades, from whom all descriptions of Electrical and Engineering Plant, Apparatus, Instruments, and Accessories can be obtained.

Advertisers are entitled to entries in this List *free of charge* according to the size of their Advertisement. Additional entries are made at a low charge, particulars of which will be forwarded on application to "The Publisher." Bold Type entries or additional matter can be arranged for with the Publisher.

AGENTS (Electrical). PAGE
Aylmer, R., 47 Victoria-st., London, S.W. ..... —
Berend (O.) and Co., Dunedin House Basinghall-avenue, London, E.C..... —
Agents for Messrs. Hartmann and Braun, &c., &c.
Conze and Simon, 52, Queen Victoria-st., London, E.C. 15
Agents for "Constantia" Incandescent Lamps, &c.
Dennis (W. F.) and Co. 23, Billiter-street, London, E.C..... 1
Agents for Messrs. Felten & Guilleaume & Antwerp Telephone Works.
Espir, F., 8, East India-avenue, London, E.C. ..... —
Agent for the Hungarian Incandescent Lamp Company.
International Electric Company, 55, Redcross-street, London, E.C. 27
Agents for Mix and Genest (Limited), Berlin.
Levi (J.) & Co., 97, Hatton-garden, London, E.C..... 30
Agents for Jules Richard, Paris.
Pope and Boddy, 26, Pall Mall, Liverpool ..... —
Agents for "Venloo" Incandescent Lamps.
Pritchetts and Gold, Soho Square, London W.C..... 22
Agents for Royce's Suspension Holders, &c.
Quicke, C. F., 72, Finsbury Pavement, London, E.C..... 22
Agent for Messrs. Connolly Bros.
Schwarte and Hammer, 8, East India-avenue, Leadenhall-st, London, E.C.. —
Agents for Heddernheimer Kupferwerk and Rheinisch-Westfalische Kupferwerke.
Schölzig, Oscar, Dashwood House, London, E.C. ..... —
Agent for the De Khotinsky Lamp.
Venner and Sillar, 10, Delahay-street, Westminster, London, S.W. 12
Agents for Chamberlain and Hookham, and for Pritchetts and Gold.
Wilhelm and Co., 132, Wool Exchange, Coleman-street, London, E.C..... 15
Agents for "Hard" Incandescent Lamps, Weinert's Arc Lamps, and Messrs W. Kücke & Co.

ACCUMULATORS. (See also BATTERIES).
Chloride Electrical Storage Syndicate, 16, Victoria-street, London, S.W. 6

ADDRESSES.

JULIUS SAX & CO., Ltd., Electrical Engineers and ELECTRIC LIGHT CONTRACTORS, RIDGMOUNT STREET, STORE STREET, LONDON, W.C.
Established 1855.

Specialities—Electric Bells, Burglar Alarms, Fire Alarms, Watchmen's Clocks and Fire Indicators combined, Water Gauges, Billiard Markers, Electric Vanes, Lightning Conductors, Speaking Tubes, Gas Lighters, Electrical Testing and Telegraph Instruments, Electrical Torpedo Apparatus.

Automatic Call Bells for Fire Stations, &c., fixed at all Stations under the control of the Metropolitan Board of Works.

Cell Calls for Police Stations, Prisons, &c., as devised for and adopted by H.M. Home Office. Contractors to H.M. Post Office and War Office.

Electric Lighting—Domestic and Public. Estimates Free on Application. Eight Prize Medals awarded.

Telephone No. 3843. Telegraphic Address: "*Sax London.*"

LAING, WHARTON & DOWN, 82a, NEW BOND STREET, LONDON, W., Electric Light Engineers and Contractors. Manufacturers and Suppliers of every requisite for Arc or Incandescent Lighting, Dynamos, Lamps, Switches, Electroliers, Brackets, &c. Specialities in Primary Batteries for Electric Lighting, Venetian Shades and Glass, Carbons, &c. Temporary Lighting on any scale at short notice. Estimates free. Telephone No. 3602.

ADDRESSES.

PATERSON and COOPER, Electric Light and Power Engineers. Contractors to the Admiralty.

Specialities—Phœnix Dynamos, Phœnix Arc Lamps, Special 5-Ampere Arc Lamps, Ship Lighting Plant, Phœnix, Cardew, Ayrton-Perry and other Ammeters and Voltmeters. Richard Frères' Recording Instruments. Sole Licensees of the Smyth-Payne Tubular Safety Wiring System, and Proprietors of the Hermite Patents for Bleaching and Disinfection. POWNALL ROAD, DALSTON; and 68, VICTORIA STREET, WESTMINSTER.

LAURENCE, SCOTT & CO., Ltd., Electrical Engineers, Manufacturers, and Contractors, Gothic Works, NORWICH. Telegrams: "*Gothic Norwich.*" See Advt., page ii., in last and next issues.

Specialities—THE SCOTT-SISLING SYSTEM is the best for all installations using accumulators; Circular sent on application.

THE NORWICH DYNAMOS are amongst the very best, Electrically and Mechanically. Numerous repeat orders prove superiority.

THE NORWICH SHIPLIGHTERS never give trouble.

SCOTT'S PATENT METER is accurate through a wide range.

COMPLETE CENTRAL STATIONS for Light and Power.

SCOTT'S PATENT INSTANTANEOUS FUSES are the best.

THE PEOPLE OF THE MOON.

A Novel. By TREMLETT CARTER.

Illustrated by D'AGUILCOURT.

"There is so much of the marvellous in Mr. Tremlett Carter's book, that at length we cease to be astonished at anything he chooses to tell us. A skilful use of scientific facts gives to the narrative a partial sense of verisimilitude. The book is boldly conceived and well written. The illustrations are of considerable merit."—*St. James's Gazette.*

"Electricity plays a very important part in the story, and the various uses to which it is put are both interesting and instructive, and doubtless are but forecasts of what will be some day. The book is well got up, and worth reading as fiction combined with possibility."—*Western Morning News.*

"It is a book of marvels."—*Yorkshire Post.*

"Tremlett Carter has a fantastic imagination, and takes his readers through many strange experiences."—*Black and White.*

"There is imagination in this story, as well as skill in the telling."—*Daily News.*

"There is a power of fantastic description in the book that suits the curious scenery of d'Aguilcourt's illustrations."—*Daily Telegraph.*

"The tale is thrilling in the extreme and cleverly worked out."—*Graphic.*

"The reader will travel through a strange country indeed, and among an almost bewildering variety of marvels. The people of the moon seem to have carried scientific research and invention to a pitch at which we poor earth mortals can hardly hope to arrive in the course of another thousand years or so."—*The Electrician.*

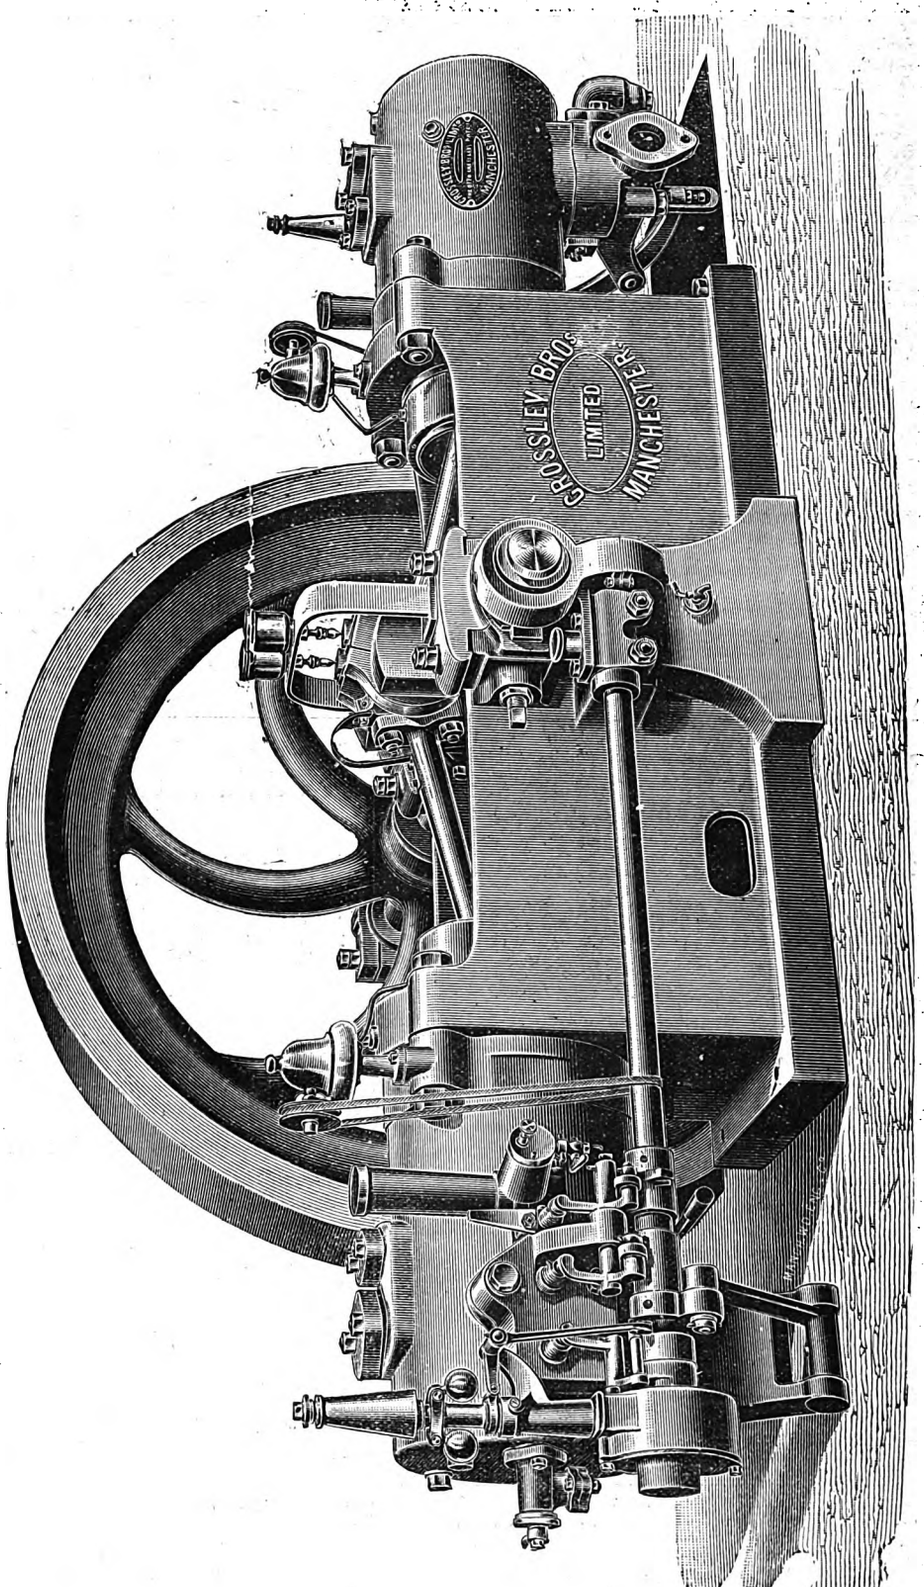
CROSSLEY'S "OTTO" GAS ENGINE

For ELECTRIC LIGHTING.

SPECIAL DESIGN OF

High-Speed Electric Light Engine,

With extra heavy Fly-wheel and Out-end Bearing.



Gives 28 Brake H.P. (Maximum) when working with Coal-Gas.

Speed, 250 Revolutions per Minute.

CROSSLEY BROS., Ltd., Openshaw, MANCHESTER.

LIVERPOOL—Oldham Place, Renshaw Street. **BIRMINGHAM—58, Water Street.**
NOTTINGHAM—King John's Chambers, Bridlesmith Gate. **GLASGOW—Great Western Road, Kelvinside.**

Also Contractors for underground Mains at ABERDEEN, COATBRIDGE, BURNLEY, LANCASTER, HUDDERSFIELD, SHEFFIELD, HULL, OXFORD HANLEY, CHELSEA, &c., &c.

The CALLENDER COMPANY is prepared to undertake the laying of Underground Mains, including all excavation and reinstatement of paving, building boxes, feeder points, or transformer chambers, erecting lamp posts, pillars and all other accessories required for the complete equipment of the distribution network of a Central Station, for either HIGH or LOW TENSION with CONTINUOUS or ALTERNATING CURRENTS —

1. With Vulcanised Bitumen Cables laid solid in Bitumen.
2. Or Drawn into CALLENDER-WEBBER or CALLENDER-RAWORTH Conduits, or into Pipes.
3. With Lead-Sheathed Cables, either Single Conductor, Concentric, or Triple Concentric, armoured and laid direct in the earth.

its constituents. As to the correctness of this assertion, we have no desire to be dogmatic; but the unedifying events of December last were certainly symptomatic of a marked divergence of opinion between the Council and the members. Mere alteration of mechanism cannot, of course, by itself entirely prevent the growth of a separatist spirit, the proneness of those in office to treat those outside as children who rarely know what they want, and when they do know ought not to have it, is too natural an instinct for that; but alteration of mechanism would have a distinct tendency that way, and seeing the *tracasseries* which have arisen from this cause, one would have expected that any remedial suggestions would have been welcomed and promptly adopted. No doubt there is much to be said, especially from the Machiavellian point of view, in favour of allowing the "malcontents" to stew in their own juice—to use the not too elegant phrase of an ex-Cabinet Minister—but after what has happened, the balance of statesmanlike advantages surely lies in winding up the present session by making such reasonable alterations in the Articles of Association as will satisfy the reformers. The Institution of Civil Engineers is always being quoted as an example. Well, let us follow it. Not only is its mode of electing Council rankly democratic compared with our own, but a week or ten days ago a number of revolutionary proposals were carried in an afternoon. If the alleged discontent be but the "baseless fabric of a dream," if those who have taken a prominent part in the reform movement are actuated by no other motives except a desire to annoy others and to advertise themselves, if they have no one behind them, the policy of permitting the agitation to fizzle out would be the only one worth considering. Without an open trial of voting strength, a course which in the best interests of the Institution cannot be too strongly deprecated, it is confessedly impossible to tell exactly how far the general body of members are prepared to support any demand for alterations in the Articles of Association: so far as our own inquiries go there would seem to be considerable bottom to the agitation. If that be so, the movement will only fizzle out to flare up later on, and the Council may encounter the awful end of the nigger who sat on the safety-valve. With the voting power of Past-Presidents abolished or greatly diminished, with a more rapid passage of members through the Council, with the election of Council somewhat more in the hands of the members, and the business at the Annual General Meetings, at which the accounts as well as the report should be presented, made less of a time-wasting formality, all will have been done that suitable lubrication can do to make the machinery of the Institution run silently and smoothly.

Assuming that the wishes of the majority of the Council coincide with those of the energetic constitution-mongers who have lately been so much in evidence, an assumption which we have some reason to believe is not without a foundation in fact, what we are going to do with this brand new machine when we get it? Is the net outcome to be merely that a few more self-sacrificing gentlemen will have an opportunity of sitting at the Council Board? Is the pace of the procession through the Council Chamber only to be quickened, and not the pacet of he Institution as a whole? If so, many a "malcontent" of to-day will wonder "*que diable allait il faire dans cette galère.*" The main object for which the Institution exists is, as stated in its Memorandum of Association, to promote the general advancement of electrical science and its applications and to facilitate the exchange of ideas; an object which it is proposed to attain by holding meetings, promoting exhibitions of electrical apparatus, publishing reports of its proceedings, forming a library and making "grants of money, books, apparatus or otherwise for the purpose of promoting invention and research in electrical or telegraphic science or its applications or in subjects connected therewith." It is in the hope that these high aspirations will be more worthily fulfilled than heretofore, that many have set their hearts on improving the administrative machinery. It is true that increased activity will inevitably involve increased outlay, and the question of ways and means will have to be carefully gone into, but with an actual annual surplus of over £1,200, and investments without any earmark amounting to a total of nearly £5,000, there is already a satisfactory fund to draw upon.

Let us consider seriatim the items enumerated in Clause B of the Memorandum of Association. The Institution certainly holds many meetings; but there is a very decided opinion abroad that it does not secure the Papers it should, an opinion not likely to be altered by the Papers presented since November last. A clearer conception on the part of those whose duty it is to glean Papers as to what questions are the "live" questions of the day would tend to improve this state of things, and a little more generosity in the matter of preparing diagrams, a somewhat more lavish outlay on premiums, and a greater energy in securing the attendance of competent speakers would not be amiss. The Royal Meteorological Society in England, and the Société Française de Physique in France, and many other societies at home and abroad, make a great feature of their exhibitions of apparatus; electrical science as in England has as yet not, we are thankful to say, reached the stationary state, and it is permissible to think that such exhibitions held in a suitable manner, in a suitable place, and at a suitable time would be much appreciated. Again, when the Institution has at last succeeded in housing itself, is it too much to expect that an institution laboratory may be founded, in which experiments and tests such as the Institution of Mechanical Engineers, the Iron and Steel Institute and the Society of Arts promote, may be carried out to the benefit of the industry at large? A system of local meetings held simultaneously with those in the metropolis, a system which is in vogue in America, is another departure worthy of a little consideration; it would assist to strengthen the connection between the Institution and its provincial supporters. There is nothing revolutionary, nor indeed particularly original, about any of the suggestions we have thrown out; they have one and all been tried and found—useful. But an institution, to justify its existence, should perform at least one function better than or different, to that performed by any other similar society. What is to be the distinguishing feature of the Institution of Electrical Engineers?

TELEPHONE EXCHANGES AND THEIR WORKING.

The following is an abstract of the discussion on Mr. Dane Sinclair's Paper, which took place at the Institution of Electrical Engineers on Thursday evening last week. Speakers who have returned their proofs are denoted by an asterisk:—

*Mr. J. E. KINGSBURY said Mr. Sinclair brought forward two rather important suggestions with the view of improving the telephone service and to some extent reducing its cost. It was open to some of them to feel that there were other ways of attaining those results, and they might even go so far as to remark that by Mr. Sinclair's methods the results he aimed at were not attained. In the first place he would refer to the call-wire system. Of course the call-wire system was by no means a novelty. It was described in that room by Sir Frederick Bramwell on March 1, 1883, when he said "The Law system seemed to me to work extremely well when I saw it in operation in Philadelphia"; and that opinion was an opinion that was held by a great many others at that day. He did not think he

Digitized by Google

had ever come across an advocate of the Law system, which was practically the call-wire system, who had not consistently held that it developed the service. But they had to consider that some experience had been gained between 1883 and 1896, and it had happened that that system which Sir Frederick Bramwell saw at work in Philadelphia was now in process of being discarded. In October, 1883, Mr. T. D. Lockwood was attending a convention in St. Louis. The Law system was under discussion then. Mr. Lockwood said? "About a couple of months ago I was in St. Louis, where the Law system has been in operation for some years. St. Louis, although a city of very large population, has a very small telephonic population. Whether there is any connection between the two things, the Law system and the sparsity of the telephonic subscribers, I am not prepared to say." In looking up that extract a suggestion occurred to him (Mr. Kingsbury) which he followed up. He looked up the English records, and there were some very full records in the Parliamentary Committee's report. Perhaps he expected to find that the English towns were also sparsely populated telephonically, but he found that it was not so. The few towns using the Law system stood at present very well on the list of those towns that had a fair number of telephone subscribers. But he found one set of records in this Committee's report—a statement showing the number of subscribers in the four large Scotch towns during the last five years. Of these towns Dundee and Aberdeen had been using the Law system during that period; one of the towns (Edinburgh) had been using the indicator system, and another, Glasgow, had been using both during the period. Now, the number of subscribers in Aberdeen during the last five years had increased 82 per cent., Dundee had increased 57 per cent., and Edinburgh 140 per cent. Four towns were not, of course, sufficient to afford a conclusive basis of comparison. Still there was the fact. In Glasgow, since the Law system was introduced the proportion of increase had considerably fallen off; but there again the time was not long enough to enable them to judge fairly. In Philadelphia the Law system was now in process of being discarded, and in St. Louis also it was going to be discarded. These were points peculiarly adapted to consideration on the subject of this Paper. Another thing he looked at from the statistical point of view was to find the extent to which subscribers used their telephones on various systems. He found that Glasgow had 6½ calls per day per subscriber, about half the number in Liverpool. That was another point they had to consider, if the Law system was considered useful to subscribers they must consider how much they used it. It appeared that on all the exchanges using the Law system the subscribers did not use the telephone to the same extent they did on the indicator system. Mr. Sinclair referred to the difficulty in connecting between exchanges, of making trunk calls. He supposed the thick and thin advocates of the Law system would say that difficulty did not exist. But they knew that it did, and its existence seemed to him rather a reason for not pursuing the Law system. If they were to indulge in any ideals at all they ought to have an ideal that the communication between towns in the sweet by-and-by would be as easy as the communication between streets of one town now, and if a system involved any difficulty in this direction it seemed to him something of a reason for not pursuing that system. Mr. Sinclair said that 95 per cent. of the subscribers appealed to in a certain exchange preferred the call-wire system to the indicator system previously in use. The weak point about that was that they had not the whole of the material before them to enable them to make up their minds. The question was, what was the indicator system previously in use? When they had that information they could estimate the value of the subscribers' opinions. Personally he attached more value to the opinion of Mr. Sinclair, as that of an engineer; the opinions of the subscribers was rather a weak argument. Subscribers ought to be treated rather as children; they did not know what was good for them. The next important point in Mr. Sinclair's Paper was the question of flat boards. In regard to flat boards Mr. Sinclair remarked somewhere in his Paper that they had been in use previously, and as they were not used for saving spring-jacks it was difficult to see what they were installed for, excepting that they were more easy to operate. That was rather begging the question. He thought it was possible to find another reason for making flat boards without suggesting that they were easier to operate. Flat boards were originally introduced on the Law system before the introduction of the multiple switchboard. At that time it was necessary to have inter-communication by what was called "cross connections" between one set of subscribers and another. Now if they could have a number of plugs along the middle of the table and operators on each side, they could reduce the number of cross connections. That was at first the advantage of the flat board. Subsequently when the Law system was extended so as to use the multiple switchboard, the jacks were reduced to microscopic size, more or less like honeycomb, and the operators were given the whole of the jacks in the exchange. If that pointed to anything it pointed to the difficulty of one operator passing another on the flat board. He would like to point out that the comparisons on paper of the upright board with the flat board had one disadvantage; they assumed one might take anything from the upright position and place it in a flat position and have similar conditions. They had only to consider what would be the difference to them if the diagrams before them were taken down from the wall and placed on the table; they certainly would not be able to see them so well. If they applied the same argument to the blackboard they would be getting very near the conditions with switchboards. If anyone would try to cover that blackboard, lying flat on the table, with chalk marks they would find it impossible. He therefore wanted them to see that the different comparisons of this Paper were not founded on fact, but were based on a wrong assumption, and he would remark that the controlling factor in this matter was not electricity at all, it was simply anatomy. If they would regard the hand as the extremity of a lever of which the shoulder was the fulcrum, they would see that the hand could describe a complete circle moving in a vertical direction, and in a horizontal direction only a semi-circle. The result was the multiple switchboard upright had double the capacity of the multiple switchboard on the flat. That was the governing factor of the whole business. It would be found also that in the upright position they had a maximum of easy work, whilst on the flat they had a maximum of difficult work. The upright board was easy to work, but the flat was difficult, and that resulted in an increased cost of working, and when they got to increased cost of working they got to the crux of the matter. They might save in the cost of construction, but only at the expense of increased cost of working. There were two points which Mr. Sinclair referred to as the most important which induced him to adopt the flat board. One was the small number of jacks and joints, and consequently the fewer faults. He was afraid Mr. Sinclair had in view an obsolete type. With the multiple form of break-jacks (Fig. 5 in the Paper *see* p. 83 of last issue), it was a distinct advantage to reduce the jacks; but that was a reason for not using that apparatus at all. But when they came to the branching system they had a condition of things in which they might multiply their jacks indefinitely, and not incur any real trouble in regard to speaking results. The next point was the possible difficulty in finding room for upright boards and the advantage of putting them on the flat, because they practically only took half the floor space required for upright boards. Well, that applied generally. If they took a multiple switchboard under ordinary conditions, with access to the back of the board, they would have a board running on three or four sides of the room. If they had a multiple switchboard on the flat they would have two operating surfaces for the switchboard. But in no case did they double the capacity of their room. If they really wanted to get a large number of switchboards into the room they must use the upright board! Take Figs. 6 or 8. In Fig. 6 they would see the cable racks went down somewhat deeply in the board. As a matter of fact in Fig. 6 the cable racks were less than one-half the distance across the board, 40in. across and 17in. down. Put that up on edge and another similar board at the back of it, and they would get two rows for less ground space occupied. The difficulties of detail in working the multiple switchboard when installed on the flat were such that it was not necessary to go into them. But there was one question he might go into, the question of an operator on one side having to read in English fashion from left to right, while on the other side the operator would have to read in Arabic fashion from right to left. Repairs were difficult and additions expensive. Then to come more to the practical question of the cost, the comparisons in the Paper were made entirely on what he might call old types. It was the question of an operator attending to 50 subscribers. The first multiple board introduced in England had one operator to 50 subscribers. Now they had boards made for 450 subscribers on the upright worked by three operators. That board was the Western Electric branching board and was established in Christiania. Boards of 360 were quite common on the branching system; that gave 120 subscribers to one operator. This arose from the facility of working, and that really was the crux of the question. They must reduce their operating expenses, taking care, of course, that the apparatus was maintained in the highest state of efficiency. They did it by using upright boards, by making them fast, by giving as many facilities as they could to the operator and reducing their whole expenses. The difference was merely a question of saving the first cost or saving the working expenses.

*Mr. BINSWANGER said he had his doubts, like many others, as to how the public would take to the call system, but from experience, he could endorse everything Mr. Sinclair had said upon the subject. He had had occasion in Manchester of using the call system and the annunciator system side by side; his own experience, and that of most subscribers whom he had consulted, was that the call system was preferable. People felt that they were in more direct communication with the exchange and with the subscribers. They got a much quicker service, but then time was the principal thing. This system also showed that subscribers would not mind doing more work, and the question of putting more work upon the subscriber led to the question whether they could not put still more work into the hands of the subscriber and thereby reduce work at the exchange and make it more automatic. He had heard lately a great deal of automatic exchange systems both in England and America, and understood that one was actually in operation in America, having 200 subscribers. Mr. Sinclair, in his paper, referred several times to American work and American invention. No doubt most of the apparatus and appliances which were used in telephone exchanges had come to us from America. This fact might give the impression to outsiders that American telephone engineers were more ingenious and more enterprising than ours in England, but the true explanation of this fact was that the early proprietors of the telephone patents had killed the industry in England in its early days. They ought therefore to be thankful to Mr. Sinclair for emancipating himself from old practice, and thus only could English manufacturers hope to regain the loss they have had in England as well as abroad.

*Mr. W. H. PREECE said that it was the first occasion on which any representative of the National Telephone Company had had the boldness to come before the Institution and to tell them what the Company was doing. Mr. Binswanger spoke rather strongly of the mode in which the industry in this country had been killed by the early promoters of this particular business. He did not think there was anybody who had ever spoken in severer terms of the management of the National Telephone Company than he (the speaker) had done in that very hall. Its management in the past was unquestionably execrable; but he was happy to say that a complete change had come over the spirit of their dreams in Cannon-row, and now they found this Company, so obnoxious in the past, actually doing all it possibly could to repair the evil that had been done, and they were now working with an energy and a spirit that would, in the course of a few years, bring the telephone industry into a position that would make it compare favourably with that of any land, not leaving out America. He gathered from Mr. Sinclair's Paper that his Company was taking the cream of what was being done elsewhere. In the first place they were

Digitized by Google

introducing metallic circuits. He had said over and over again that the telephone without a metallic circuit was an imperfect and incomplete apparatus. Again, they were introducing multiple boards. But he disagreed in regard to these with Mr. Sinclair, for his opinion was that the day of the multiple board for large exchanges was over—he would not say it was quite over, but the multiple board was doomed. The experience in America was that as an exchange grew, so did the difficulties of the multiple board. The experience in America, in Sweden, and in Berlin seemed to be that when they got to 5,000 subscribers the difficulties were so enormous that they must be met in some other way. In the States and in Berlin they were being met by decentralisation; in Chicago particularly, the system Mr. Sinclair had referred to, called the divided board system, had been inaugurated, but in San Francisco there was another system, called the "Express" system, which was also being introduced in Chicago and one or two other places. Up to the present moment the reports received were satisfactory, and it would seem that sooner or later the multiple board in all big exchanges must give place to the "Express" system. Mr. Sinclair in his Paper had spoken a good deal on the question of trunk work and its difficulties. On that point he was not prepared that night to speak. They had only within the last week or two transferred to the Post Office from the Telephone Company the whole trunk system of this country, and it would take some months before it would be thoroughly licked into shape. He hoped by the commencement of the next session they would have in this country the finest telephone trunk system in the world, and he also hoped that the session would be commenced with a Paper written by Mr. Gavey describing that trunk system and how it was being worked. Mr. Kingsbury had criticised a great deal the observations that Mr. Sinclair had made on the call-wire system, or what he called the Law system. The latter system, worked on a large scale, had its difficulties, and he entirely objected to it for the simple reason that it was absolutely unnecessary and not wanted at all. In fact he could not understand, with the experience they had had, the want of any call system or any mode of calling attention whether by the magneto or by the Law system. In the Post Office they never had such a system. Their call was automatic. A man when he went to his telephone and lifted it off the switch hook, called the exchange system, and when he had finished his talk and replaced his telephone on the handle again, there was a ring off. Both the call and the ring off were absolutely automatic. It had only one objection, and that was a very strong objection with those who had not tried it—it was not an objection to those who had tried it—and that was that it involved the use of a continuous current. The idea of having a battery running continuously on a subscriber's line was like a red rag to a bull to an old telephone man. But to a new telephone man and to the Post Office it had no terrors at all. Mr. Kingsbury had also criticised Mr. Sinclair's views on flat boards versus vertical boards. He (the speaker) had an objection to flat boards. There was a certain amount of fascination in the appearance of a flat board; it was certainly attractive, and there was something about it that was enticing. But his objection to it was purely a practical one, and that was the difficulty that an engineer had in removing faults while the operators were at work, and the difficulty of making any changes behind the board. With a panel or a vertical board there was absolutely no difficulty. The operators proceeded in the ordinary way, and the engineer went behind, examined his contacts and his springs, and he could alter and change and shift, without anybody in front having the least idea there was anybody behind. There was one other point that he wished to urge, and it was this, that they might make their apparatus as perfect as the apparatus described by Mr. Sinclair and the apparatus he had seen in use in Sweden and in Berlin. They might have adept operators, but unless they had subscribers who were equally clever in the manipulation of their apparatus, and unless they had subscribers who took an interest in the telephone work of their offices, and unless they had subscribers who would co-operate with the telephone company or the Post Office department, or whatever it might be that did the work; until they got mutual forbearance, mutual assistance and support from each side, they would never create satisfactory telephone working in this country. He could say without the slightest hesitation that there was no place that he had ever visited where the telephone work was better done than it was in Berlin, and they had it well done there on a system that was technically defective. It was a system consisting of a single wire—it was a system where they used practically obsolete apparatus. The reason was this, there was absolute co-operation between subscriber and operator, and half the work was done by the subscriber.

Mr. G. L. ADDENBROOKE said he himself was connected with the telephone company from 1883 to the end of 1886, nearly four years, and during that time he thought the telephone company might be said to have got into shape. He had always felt, speaking commercially as a user of telephones, that an extremely rapid service was of far less moment to commercial men than thoroughly good speaking. The question of whether they had to wait five minutes, or ten minutes or a quarter of an hour was nothing to the necessity of being able to speak thoroughly well. There certainly was a great improvement in the London work through the adoption of the double-wire circuit, but it was lamentably behind the service in the country, and in the country the telephone was of less importance. As regards co-operation of subscribers, that was no doubt a very technical matter, and he could appreciate the position the Company took up. He thought Mr. Sinclair had hardly done justice to previous work in the few remarks at the latter end of his Paper. Mr. Sinclair said he had found it necessary to have a central trunk service for London. Of course that was literally true, but he thought not quite in the manner people would gather from the Paper. The trunk service was established about 10 or 11 years ago. Towards the end of 1883 or the beginning of 1884 the question of trunk communication began seriously to crop up owing to the difficulty of getting through to other exchanges, particularly to some of the Eastern exchanges and those in the City. The matter was debated for some time and a meeting was held at the Euston Hotel Mr. Morgan was the Managing Director at that time. He (the speaker) did not know how he got to that meeting, but he was there although he took a very small part in the discussion. Practically at that meeting the trunk system was decided on, and it was put into practice in a few months. Their board was designed by Mr. Hawes, and the London exchange system was really put down on a basis which had gone on ever since. Therefore it was only fair that some credit should be given to those who really did initiate that service.

Mr. F. B. O. HAWES said he was himself no longer connected with telephony, but he had always felt that there was a great dearth of papers of this kind. He hoped they would have many more of them. There were one or two points regarding which he would like a little more information than Mr. Sinclair had given. In London at the present time call wires were used between the exchanges for working trunks or junction wires, and he thought it would be useful if Mr. Sinclair would tell them what proportion of trunks they worked in that way. That was to say, how many junction wires one call wire served. Another point about which he would like to hear was as to the motors used in the exchanges; the generators for the ringing currents were, he believed, driven by small motors, and it would be interesting to learn what motors were found most serviceable. As to flat boards he did not agree with the points Mr. Sinclair had urged in their favour. The United Telephone Company were the first in England to use multiple switchboards. They were designed by the speaker, and were intended to be used in an upright position, but at Mr. Clay's suggestion they were used lying down, and the reason for that Mr. Sinclair said he did not quite understand. In those days they had no experience of how many subscribers one operator could attend to on a multiple board, and they had thought they had better err on the right side, and so provided one operator for each 50 subscribers, by fixing the boards lying down. This, as it turned out, proved to be more operators than was required, and they would have worked much better standing up. Having been designed for use upright, several of the contacts were affected by dust, and there was some trouble from that cause. Still, at the same time, the disadvantages of the flat board were not fairly shown in that case. They also had trouble about repairs, and he could not see how any flat board got over that trouble. A system had to be constantly worked now, and therefore if they had to do any repairs it must be while the switchboard was at work. Coming to the question of fitting up the boards, when a board was started with a certain capacity new jacks would have to be added from time to time when enlarging the exchange, and the addition of those jacks while the boards were in use was a tremendous piece of work. With the flat board it was almost impossible to get openly at this work and to see what one was doing satisfactorily. The difficulties, he should say, were enormous. Dealing with the size of the board, and taking Mr. Sinclair's figures, it appears that a switchboard on the flat system for 6,000 subscribers would be one yard square. Now, if they took a table a yard square, and tried to sit on one side and reach over to the opposite corners, they would find it almost, if not quite, impossible. They would have to stand up to the work, and if an operator had to keep on jumping out of her chair for a large proportion of calls it would not help to expedite matters. Another matter he would like Mr. Sinclair to tell them about from his experience was as to the cords getting entangled as they came down on the board. It was certainly the case with the board of which he had had experience. It appeared to him that in pulling out one cord they would be very liable to pull out another with it. Mr. Kingsbury referred to the dirt getting in to the flat boards, and he (the speaker) thought it was a serious matter. He would go further than Mr. Kingsbury went, and would say that whatever sort of multiple board was used the dirt would cause leakage from line to line; they would get the same amount of cross talk from line to line through dirt, whether it was the one-series system or the arc system. He thought a little more might have been said about the "Up" and "Down" trunk wires with advantage. At first sight, with junction wires between two exchanges, it would appear to be most economical to use them irrespective of what class of calls was put on, whether from B to A or from A to B; but when they considered the matter further, and looked into the details of the work, it was very evident there was a great benefit in dividing up the trunks. He fought very hard for that in the old days, and at last got it done. The advantage was that, although they were not using them quite as economically in one respect, they could use them much quicker, and so get more work out of them. Talking about working quickly, Mr. Addenbrooke's remarks about time not mattering must be received with some caution. As Mr. Addenbrooke had also remarked, the central junction exchange was a very old idea indeed in London, and it was an idea which very many people he knew claimed as entirely their own. Mr. Preece had referred to the "Express" system in Chicago. In London they had something approaching the "Express" system. The National Telephone Company had a system which connected stockbrokers together, and that system he had always heard was a perfect one. It was held up very often as being an example of an ideal exchange. That exchange he believed was worked by a very ancient apparatus discarded from other exchanges, and it was merely due to the fact that there were no junction wires, and only a small number of subscribers that the service was so extremely rapid. Then there was the question of the subscriber doing the work of ringing up himself, as Mr. Preece had described was the case in Berlin. When a subscriber had a lot of work to do himself, he did not notice the time that elapsed so much as if the operator did it, but the speaker thought the latter was the most rapid. But there was this disadvantage about that, that supposing the connection was made, the subscriber might go on ringing until he was black in the face without result.

Mr. G. J. SOMERVILLE said Mr. Sinclair had mentioned as a weak feature in the American divided board that no connection was made without being dealt with by two operators. It was certainly a very weak feature of any board at which one operator could not complete any connec-

Digitized by Google

tion asked for. This difficulty was not altogether absent, however, from the multiple boards used generally in this country. They were informed that the length of each section on these boards was 6ft. 6in. It therefore followed with the upright boards that an operator was expected to stretch a distance of 3ft. 3in. from the point opposite which she sat, and that ought to be done without any inconvenience to her neighbours or interrupting their work. She might be able to accomplish it if she had plenty of room, but they had to remember that there were four operators sitting in front of each section, so that the space allotted to each was only 19½in. In the case of flat boards the matter was even worse. They had been told the width of the board was 40in. To make some connections an operator therefore was called on to insert a plug in a jack which, being on the opposite side of the board, was not less than 4ft. distant from where she sat. Taking into account that there were eight operators working at the same section, and that a plug and cord had to be passed between the other cords in use at the time, he thought they would agree that the operation was nearly impossible. In practice the operator did not attempt it, but asked for and received assistance in making nearly 25 per cent. of the connections required, so that the weak feature mentioned was not by any means absent from the switchboards in use in the National Telephone Company's service. Reference has also been made to the listening keys. These are used to connect the operator's telephone to the subscriber's wire. Of course some means are necessary for this purpose, but those now universally used by the National Telephone Company are not good, as they were responsible for introducing into the system a very grave defect. With this key the operator had the opportunity of overhearing any conversation which was carried on by the subscriber for whom she had made the connection, or in fact any conversation passing through the exchange. It was useless to say that it was never used for that purpose; it could be so used at all times, and is thus the source of one of the very worst defects which can exist in any telephone system, viz., the absence of secrecy. It was also to this key, as at present used, that subscribers were indebted for the annoying interruptions and continual questions by the operator "Have you finished?" He was very much pleased to hear Mr. Sinclair assert that he was an advocate of the use of flat boards and the call-wire system; although, judging from the results, he should imagine that until quite recently his advocacy must have been of a very mild type. It is the Mann system that is being introduced into the National Exchange in Manchester, and from the way Mr. Sinclair now praises this system, doubtless he will by-and-bye advocate its use even in London. His objection to its being introduced here is without foundation. The real difficulty is in connection with the static capacity of the signal wires, but that can be overcome, and t' ere is no reason for the operator at King's Cross, when desiring to communicate with Lime-street, doing either of the two things he says are inevitable, viz., to cut herself off from her own call-wire, or to join her call-wire with its 50 subscribers to the call-wire to the city.

*Mr. DANE SINCLAIR, in his reply, said Mr. Kingsbury condemned the call-wire system. If he took his experience of it from the Law system he (the speaker) did not wonder at it. When he (the speaker) first joined the telephone service in Glasgow the Law system was then at work, with 200 or 300 subscribers, and was so unsatisfactory that after eight months it was turned out. But in this, as in all other things, there had been developments. There came along the Mann system. This made a deal of difference. The difference was that with the Law system, as first used, every subscriber had the power of breaking into the circuit and cutting off all the subscribers on the other side of him. That and the make-and-break in his apparatus more than counter-balanced the advantages. When they came to the other call-wire system the subscriber could no longer break in, but had to wait his proper turn, which made all the difference. In a great centre of the size of Glasgow it was necessary to go into it fully, and he could tell them that at a meeting of experts called from all parts of the country it was laid down that where they had an exchange with no junction wires, then—although a great many of them were opponents of the call-wire *per se*—under that condition the call-wire did give the most absolutely perfect service. Therefore, when they had an exchange with a large proportion of local work they got the advantages without the disadvantages. Coming to Mr. Kingsbury's remarks with regard to the flat board, there was really no time to go into the matter deeply. But in the days when this point was discussed a table was placed on edge, and those present were set to see whether they could reach higher stretching upwards or further when the thing was flat in front of them. It was found that they could reach further on the flat to the right hand and the left, but could not reach quite so far in front as when the thing was in a vertical position. He was standing by listening, and he came to the conclusion that there was so little difference between the two that it was absolutely academic to try and score a point one way or the other. Then Mr. Kingsbury gave many another reason why the flat was not so good as the upright, and stated that there were various difficulties. He (the speaker) supposed there were difficulties; but he had yet to live to see the switchboard with no difficulties. Therefore it came to a choice of difficulties. One speaker had said that it was a serious matter to increase the number of jacks on the flat board, because it would have to be done when it was at work. His reply was that it was not necessary to do this when at work. The few hours when they were not at work in the evening was quite sufficient. When it came to the question of the flat board in use to-day, and the upright board in use to-day, he could say conscientiously that it was a more simple matter to lift a row of jacks out of their place on the flat than to get them out of their place on the upright; but there was not very much in it. He was not going to discuss the point referred to later by Mr. Preece, the difficulty for a man to get down amongst the wires to work. It was difficult, but it was not impossible, because they were carrying this thing out in practice. Mr. Kingsbury had referred to the fact that there were fewer calls at Glasgow with the call and flat board than at Manchester. It happened that the figures were taken on the holiday season in Glasgow, and that accounted for the fact that the Glasgow figures were so low. They all knew that Mr. Preece had advocated, and rightly so, a metallic circuit from the beginning of telephony, and great credit was due to him in that he was so early a champion of a good cause. But it must be remembered that there was the commercial element to consider as well as the engineering. When Mr. Preece spoke of Berlin he quoted the very reason why he (the speaker) liked the call wire; it threw the responsibility of actual work from off the hands of the operator into the hands of each individual subscriber, but with this difference, that if the subscriber who was called up at the other end did not respond the subscriber calling got an instantaneous reply from the exchange as to what the reason was. He was assured that he had been connected on; and that was, perhaps, the greatest reason for the success of the call-wire as compared with the battery system. When the signal was given to the exchange, they wanted an absolute certainty that when they did something they would get something. With the ringing system they might call and the indicator might drop, but the operator was going to answer when she was ready. He did not mean for a moment to suggest that the operators did not answer as quickly as possible, but as between the two systems, in the one case the subscriber commanded the situation, and in the other—well, he did not. With regard to the central trunk exchange idea, it was after a little time, like many another good system, carried too far, and in practice they had to undo a great deal of it. They found, taking two small exchanges in the suburbs of London, that the wires must run into some central point, where they would command the ability of being joined on with other exchanges. But taking any big city with 20,000 calls per day between two exchanges, could anyone explain what was gained by putting all those calls through a third point or exchange? When it was looked into it was found that only one central exchange was required for the *overflow* work between the great exchanges and for branch exchanges; that was the system that was being worked out in London to-day. As he had said in the Paper, any exchange which had 40 messages from or to any other exchange was provided with direct junction wires, but if the messages were fewer than that they went through the central exchange.

OBSERVATIONS ON ISOLATED NERVE.*

BY AUGUSTUS D. WALLER, M.D., F.R.S.

The present investigation arises from experiments undertaken to determine autographically the varying relations between the magnitude of electrical change and the magnitude of stimulation in nerve under various chemical conditions.†

The main principle upon which the inquiry is based is the proposition established (by Du Bois-Reymond, and by Hermann in particular) to the effect that disturbed protoplasm is electro-negative to the normal. An accessory principle, to which reference will also be made, is that upheld (by Hering in particular) to the effect that protoplasm in which disturbance has just ceased is electro-positive to the normal. In accordance with the first principle, injured is electro-negative to normal protoplasm, and excited is electro-negative to resting protoplasm. In accordance with the second principle, recently excited is electro-positive to normal protoplasm.

Nerve (the excised and still living nerve of the frog) is, for the purpose of this inquiry, considered as a convenient strand of excitable yet hardly exhaustable protoplasm, giving off to the galvanometer a demarcation or injury current (Hermann) from a less disturbed portion (longitudinal surface L) to a more disturbed portion (transverse section T), which current, during disturbance of the whole nerve effected by weak tetanisation at the two exciting electrodes, but principally affecting a less disturbed portion L, undergoes a negative variation (Du Bois-Reymond), the magnitude of which is taken as the index to the magnitude of chemico-physical change aroused in the nerve under various chemical conditions.

Care is observed to avoid the ordinary fallacies and to obtain a "negative variation" as far as possible clear of electrotonic effects. Action-currents (significant physiological effects in nerve) are distinguished from physical effects by means of anæsthetics, CO_2, Et_2O, $CHCl_3$. ‡

The physiological state of the nerve is tested by tetanising currents of low and uniform intensity, of uniform duration (7½sec., and later 15sec.), at uniform intervals (1min.), in both directions. The series of negative variations or action currents led off to the galvanometer, gives a corresponding series of deflections, which are registered on a slowly-descending photographic plate.

The plan of procedure adopted throughout has been to take for a period a normal series of deflections, then to submit the nerve to the action of a reagent (without removal from the electrodes in the case of gases, but with such removal in the case of solutions), finally to take for a further period the series of increasing or decreasing or reversed deflections of the chemically-modified nerve. Alterations of resistance were controlled by aid of a standard

Digitized by Google

deflection of 0 001 volt let into the nerve and galvanometer circuit at beginning and end of experiment.

The results so far acquired may be considered under the following heads:—(1) The effects of anæsthetics and of some gases. (2) The effects of several chemical substances in solution. (3) The effect of carbon dioxide. (4) Theoretical considerations.

(1) *Anæsthetic vapours* were employed at the outset of these observations with a view of distinguishing between physiological and physical effects.

(2) *Action of Reagent Soluble in Normal Saline.*—The nerve is bathed for one minute in more or less dilute solutions (acids, alkalis, neutral salts) and replaced upon the electrodes. Distilled water gradually abolishes excitability. Dilute acid solutions, M/40 to M/10, cause primary augmentation, followed by gradual diminution. Stronger acid solutions, M/10 to M/5, cause primary diminution and abolition.

Alkalis.—Caustic potash is far more active than caustic soda. Potassium salts are more active than sodium salts.

Neutral Salts.—The influence of the base predominates in a total action due to the entire molecule. Calcium chloride in M/10 solution augments the electrical response, and antagonises potassium chloride, which diminishes or abolishes it. Mercuric chloride is the most lethal of any salts hitherto tested; its M/100 solution abolishes the response. Isomeric compounds differ in efficacy.

ON THE BEHAVIOUR OF ARGON AND HELIUM WHEN SUBMITTED TO THE ELECTRIC DISCHARGE.*

BY J. N. COLLIE, PH.D., F.R.S.E., AND WILLIAM RAMSAY, PH.D., F.R.S.

The experiments to be described fall into two classes; the first series relates to the distance through which electric sparks from an induction coil will strike through argon and through helium at atmospheric pressure, contrasted with the length of the spark-gap in other gases; and also with the pressures at which the spark-discharge changes into a ribbon-like discharge in different gases. The second series, which was made with the object of ascertaining how much of one gas is detectable in its mixture with another, at different pressures, deals with the spectra of gases in electrodeless vacuum tubes. As both sets of phenomena relate to the passing of electric discharge through gases, we have thought it well to consider them together.

The attention of one of the authors was drawn to the spark-gap, as a possible means of obtaining information regarding the atomicity of argon and helium, by Mr. Natterer, who was kind enough to send copies of his Paper on the subject†. Natterer's conclusion, drawn from a great many experiments, was that the spark-gap at atmospheric pressure varied in length inversely as the atomicity of the gas; thus, in mercury gas, which is acknowledgedly monatomic, the distance traversed by a spark from electrodes of approximately constant potential, was very much greater than in diatomic gases, such as oxygen, hydrogen, nitrogen, or carbon monoxide; and in these, greater than in gases of more complex molecular structure. Our experiments show that while with argon the distance traversed by the spark is considerably greater than with air, oxygen, or hydrogen, with helium the spark is capable of passing through most unusual distances.

To carry out such experiments the tube must contain movable electrodes; and yet, in order to avoid contamination of the gases, they must have sealed joints. Closing with india-rubber corks appeared to work well in Natterer's experiments; but then he had large quantities of common gases at his disposal. In our experiments this was, unfortunately, not the case. The current was an intermittent one from one of Apps' large induction coils, driven by a storage cell giving about 8 volts. The hammer of the coil was not altered in position during the experiments.

It was found impossible to make measurements of the extreme possible length of a spark. After the coil had been running for some time an isolated spark generally passed, even when the electrodes were far apart. But consistent measurements could be obtained when a rapid discharge began to occur on bringing the electrodes together. It was found possible to obtain constant readings of distance to within half a millimetre, and to form an accurate estimate of the intensity of the rain of sparks, as contrasted with intermittent discharges.

The mean results are as follow:—

Oxygen	23·0mm.
Air	33·0 ,,
Hydrogen	39·0 ,,
Argon	45·5 ,,
Helium	probably 250 or 300mm.

* Abstract of a Paper read before the Royal Society.

† *Wied. Ann.*, 1889, p. 663

The tube was not long enough to obtain measurements with helium. But another tube with permanent electrodes, distant from each other 200mm., gives, not sparks, but a ribbon of flame, due apparently to the luminosity of the first spark remaining until the second has begun its journey. This band is of a blue colour, and and does not show the yellow D_3 line very brightly. The other helium lines are much more brilliant. Indeed, the D_3 line is not a marked feature of the helium spectrum at high pressure, with an unaided Ruhmkorff coil discharge.

It will, we think, be acknowledged that the length of spark in helium is a very remarkable phenomenon. To what is it to be attributed? Any attempt to answer this question must necessarily, in our ignorance of what takes place during passage of discharge through gases, be of a speculative character. And inasmuch as it is probably connected with other properties of helium, we shall postpone our attempt at an explanation until our further experiments have been described.

After these experiments had been made it was discovered that the spark discharge changes to a ribbon discharge at some definite pressure with all gases. The discovery was an accidental one. We wished to repeat the experiments on the helium ribbon, and the tube was filled with the first sample of helium that came to hand; it had been prepared from bröggerite, and had received some contamination from air and nitrogen. To our surprise we failed to obtain a ribbon discharge at ordinary atmospheric pressure; only a rain of sparks could be seen, and it was not until the pressure had been lowered by several hundred millimetres that the discharge became ribbon-like. This observation led to experiments, of which the results are summed up in the following table.

Gas.	Pressure of changes of character of discharge.
Air	73 or 74mm.
Hydrogen	42 or 43 ,,
Oxygen	81 ,,
Carbon dioxide	92 or 94 ,,
Cyanogen	23 ,,
Nitrogen	33 ,,
Carbon monoxide	49 ,,
Helium	1,270 ,,

These phenomena are, without doubt, very complex; but one fact is unmistakeable: that helium presents a behaviour very different from that of all other gases. In short, a tube like those termed "Plücker's tubes" need not be filled with helium at a low pressure, but shows all the phenomena of a vacuum-tube at ordinary atmospheric pressure. The order of arrangement of the other gases, moreover, is not the same as that which obtains with the shower of sparks passing through the gas. This may be due to some molecular change due to lowering of pressure; but such a supposition is of a purely speculative character.

Our next series of experiments relate to the visibility of the spectrum of one gas in presence of another. The gases employed were hydrogen, oxygen, nitrogen (atmospheric), argon and helium; our primary object was a practical one—to ascertain whether the spectrum affords an adequate test of the purity of the gases. For example, if the spectrum of nitrogen is no longer visible in a mixture of argon and possibly nitrogen, can it be assumed that nitrogen is wholly absent? How much must the percentage of nitrogen in such a mixture be reduced before the spectrum disappears?

Broadly stated, these experiments show that while relatively large amounts of helium and argon require to be present in hydrogen and nitrogen before their spectra become visible, an exceedingly minute amount of hydrogen or nitrogen is visible in helium or argon; and that a rise of pressure increases the visibility of nitrogen, both in helium and argon. Also that a large proportion of helium must be added to argon to become visible; while a minute trace of argon is visible in helium. And combining these results with those relating to the *spark-gap* or to the continuous discharge, it would appear that at atmospheric pressure, a discharge passes much more readily through helium than through the other gases, while at very low pressures, if conveyance of current can be inferred from luminosity of spectrum, the current passes more readily through all other gases than through helium; and that a current is conveyed more readily by nitrogen than by argon.

In the present state of our ignorance on what occasions the passage of current through gases, it is perhaps premature to speculate. But accepting the hypothesis which appears to be gaining ground, namely, that a species of electrolysis takes place during the passage—a tentative explanation may be put forward. It may be supposed, as Dr. Lang has pointed out,* that a gas, such as hydrogen, at atmospheric pressure, is partially, but very slightly, ionised, or perhaps better, polarised; if that expression refers to atoms capable of receiving and transmitting an electrical charge.

Now, the conveyance of the current is conditioned by at least two circumstances—first, by the number of such atoms per unit

* "Dielectricitätsconstante," *Wied. Ann.*, 56, p. 543.

Digitized by Google

volume; and second, on their relative velocity, which may be taken as proportional to the square root of the density of the gas. Hence, it might be inferred that if only few atoms are present, great resistance will be offered—first, because of their fewness; second, because of the frictional resistance offered by the molecules of gas, as distinct from the atoms. It is not so easy to understand why a high electromotive force is required to overcome this resistance, unless it be supposed that the atoms capable of conveying charges neutralise each other by combination before the charge can be transmitted from one electrode to the other. Waiving this difficulty for the present, the hypothesis agrees with the known fact, that decrease of pressure promotes dissociation, where the number of ions or molecules produced by dissociation is greater than the original number of undissociated molecules; and with increased dissociation there should be, as there appears to be, decreased resistance in the case of diatomic gases, such as hydrogen, oxygen, and nitrogen.

In considering gases, presumably monatomic, such as argon and helium, we see that the former offers considerably less resistance to the discharges at atmospheric pressure than the diatomic gases; and the latter very much less. These peculiarities may be due to their monatomic character, and the great difference between the length of the spark-gap in argon and in helium may be dependent on their difference of densities, and be connected with the length of the mean free path of their molecules. When pressure is lowered these gases appear to conduct less well than the diatomic gases; and it may be that their molecular constitution is less affected, if affected at all, by diminution of pressure.

The behaviour of mixtures of argon and helium at low pressures is somewhat inscrutable. Why should argon convey current almost to the exclusion of helium if, indeed, visibility of its spectrum be taken as an indication of conductivity? In this respect argon rather resembles the diatomic gases.

It may be objected that, in making such observations, one consideration has been neglected. It is the nature of the electrodes. This may indeed play a not unimportant part in the phenomena. It is unquestionable that hydrogen and helium are both absorbed by platinum, and it would appear that nitrogen, too, can be made to combine, for it is removed from a vacuum tube containing it, if the platinum is "splashed" on to the walls. But the experiments on mixtures of gases were performed in vacuum tubes without electrodes, and the influence of the electrodes comes in only with experiments on gases at atmospheric pressures, and in those in which pressure was reduced. Their pressure may, however, conduce to some kind of polarising influence, and the conclusions, such as they are, may be vitiated by neglecting this factor.

We trust that these somewhat rash speculations will be forgiven; the subject is a difficult one, and we have carried out the experiments more with the view of obtaining practical help in recognising the purity of argon and helium than of carrying out a research on the relative conductivities of gases. There is evidently a wide field for research, and we shall be glad if this description of our methods of manipulation, and of the somewhat meagre results which we have obtained, may induce others, better qualified than we, to make similar investigatons.

CHANGE OF RESISTANCE DUE TO ELECTRIC RAYS.*

BY E. ASCHKINASS.

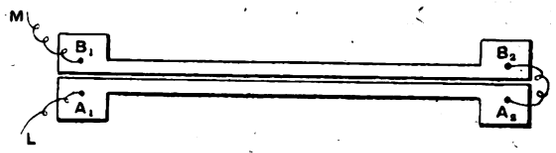
In November, 1894, I reported to the Physical Society of Berlin upon changes of resistance observed in tinfoil gratings and other metallic conductors after they have been exposed to electric radiation.† It was only after closing my work that I came across Branly's investigations,‡ according to which certain substances especially metal filings, undergo a diminution of resistance when electric sparks pass in the neighbourhood. At that time I was unable to decide whether the two phenomena were identical.

Meanwhile, Mizuno‖ has verified my observations on tinfoil gratings, and observed that the diminution of resistance does not occur when a larger interval separates the tinfoil strips. From this he concluded that the phenomenon "did not depend upon a molecular, but upon a purely mechanical" process. For the gratings are prepared by cutting a sheet of tinfoil into a large number of narrow strips by parallel cuts, the current having to traverse the whole series along a zig-zag path. Either the gratings are mounted on a frame, or the tinfoil is stuck along its whole surface upon a foundation. Now the cuts can never be made quite rectilinear, even with the sharpest knife, but the edges of the various strips always appear studded with loose metallic particles under the microscope. Now, according to Mizuno, the electric waves produce a motion of the particles in such a manner that many contacts are made at the cuts. This would lead to a decrease in the total resistance, and the phenomenon would be explained in the same manner as that of the metallic filings. Shortly afterwards Haga§ arrived at the same result.

In the following I shall myself communicate some results which show that the changes of resistance of the tinfoil gratings are indeed due to occurrences at the cuts of the gratings, and are therefore identical with the phenomenon first discovered by Branly.

A piece of tinfoil, which was mounted upon cardboard or glass, was cut along its whole length with a sharp knife (see figure). To the four ends, A_1, A_2, B_1, B_2, of the two strips binding screws were attached. First of all, A_2 and B_2 were joined by a short wire, and the wires L and M joined to A and B served to introduce the whole arrangement into the gap of a Wheatstone bridge. The current, therefore, flowed from A_1 to A_2, B_2, and B_1. Under the influence of electric waves a permanent change of resistance was observed, as before. It could be counteracted by a slight mechanical concussion. Then the junction A_2 B_2 was withdrawn, and the connection M was joined to A_2. Thus only the strip A_1 A_2 was introduced into the circuit. With this arrangement no influence of the electric waves was perceived; the same applied if the strip B_1 B_2 alone was put in circuit. Hence the change of resistance does not occur in the mass of tinfoil nor at the contacts A_1 A_2, B_1 B_2.

Next, the connections L and M were put to A_1 and B_1, and the connection A_2 B_2 was re-established. The whole was put in circuit with a sensitive galvanometer, and a feeble current was passed. The deflection of the magnetic needle was kept within suitable limits by choosing an appropriate current. Then the connection A_2 B_2 was broken, and the current could no longer pass. But as soon as electric waves were produced in the neighbourhood, the needle was deflected and assumed a new position of equilibrium. Hence the current flowed across from one strip to the other. By heating or concussion the needle could be brought back into its original position.



Different tinfoil resistances prepared in the manner indicated had different sensibilities. But the phenomenon disappeared completely when the interval between the two strips was too large. The greater the sensitiveness for electric oscillations, the smaller is the concussion sufficient to bring the galvanometer needle back to its original zero.

From these experiments it results without doubt that the changes of resistance of tinfoil gratings are due to cross contacts between the strips, and that we have here to deal with the same phenomenon as was first observed by Branly, and recently by Lodge,† Minchin,‡ Von Lang,‖ and others. The apparent changes of resistance of wires, which I had previously observed, might also be explained by the influence upon the contacts at the terminals.

As regards the explanation given by Mizuno, it does not appear to be quite plausible. For then it would be very remarkable that platinum mirrors and certain other substances show an increase in resistance§ under the influence of electric waves. Besides, I have regularly observed in tinfoil gratings and wires that before the action of the oscillations no mechanical concussions, however strong, produce any change of resistance. This can hardly be harmonised with Mizuno's theory of easily-movable metallic particles, especially since after the action only a very slight concussion is required to re-establish the original resistance. Branly also is of opinion that his experiments do not admit of a purely mechanical interpretation of the phenomenon.¶

Electric Pumping.—The firm of Apollonj have obtained from the Municipality of Rome a concession for the electrical transmission of power from some falls at Acque Albule, near Tivoli, and its distribution in the city. The power will be employed for the working of a number of small motors intended to raise the level of the Trevi waters, now distributed to supply the lower parts of Rome.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April 10, 1896.*

The American Bell Telephone Company.—The annual meeting of this Company was held in Boston on March 31st, and the report for the year ending December 31st last shows the following results: gross earnings $5,124,952, expenses $1,911,193, net earnings $3,213,759. Further statistics show that on December 31st the Company had 674,976 telephones in use, 260,324 miles of wires on poles, 12,861 miles of wires on buildings, 184,515 miles of wire underground and 2,028 miles of submarine wire, making a total of 459,728 miles. The total number of daily connections were 2,351,420. During the year the Company's leasing instruments expended for new construction $6,463,000, for addition to real estate $465,000 and for repair and construction $7,223,000, making a total of $14,150,000 applied to extension and care of the telephone plant in the United States. The principal cities and towns in most of the states east of the Mississippi River are now connected by telephone, and conversation can be held by that method over distances of 1,500 miles, which is said to be more than twice the length of line anywhere brought into use for this purpose outside of the United States. Within the last five years alone 130,000 miles of telephone wires have been placed under ground.

The Mutual Life Insurance Company of New York.—This concern announces that it will hereafter accept risks on the lives of electrical engineers at the ordinary rates, without extra premium. It defines the term "electrical engineers" as meaning consulting electrical engineers and men who have independent charge of a dynamo or holding a still higher position in connection with an electrical plant.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *April 20, 1896.*

The Electrical Exhibition of the Société Internationale des Electriciens.—This society has arranged for an exhibition of electrical apparatus on May 2nd, 3rd and 4th. The exhibits will be divided into three classes, according as they are connected with the domestic, medical or the educational side of electricity.

Société Française de Physique.—The annual Easter exhibition of this Society was naturally noticeable for the large number of Röntgen apparatus and photographs shown. Acetylene also was a prominent feature. Amongst the other exhibits shown may be mentioned that of the firm of Gaiffe et Cie., comprising a large number of electro-medical apparatus designed by M. D'Arsonval, and that of the old established works at Cail. The exhibit of the latter firm consisted of a dynamo intended for research work at the Sorbonne, giving 0·2 ampere at 3,000 volts.

Société Internationale des Electriciens.—The annual general meeting of this Society took place on April 1st under the Presidency of M. R. V. Picou. The voting resulted in the election of the following for the year 1897-8:—*President:* M. d'Arsonval. *Vice-Presidents:* MM. de Nerville, Pellat, E. Sartiaux. *Secretaries:* MM. Gosselin, Laffargue, Poincaré. *Treasurer:* M. Violet. *Members:* MM. Baudot, Brillié, Cance, Curie, Dujardin, Fayot, Grosselin, Hospitalier, Miet, Mildé, Minet, Monmerqué, Montpellier, Picou, Raffard, Richard, Street, Vaschy, Voisenah. *Financial Committee:* MM. Armengaud, Berthon, G. Masson. M. Paul Janet, who has taken the place of M. de Nerville as head of the Laboratoire Central d'Electricité, described how a voltmeter for 20,000 volts was standardised at this laboratory. The instrument in question was a Kelvin electrometer with two quadrants and an aluminium needle. In order to make the axis of suspension coincide exactly with the centre of gravity, the needle carried underneath two perpendicular axes, on which were placed aluminium nuts. Variations of the sensibility of the instrument could be afforded in the usual manner by means of weights of 28, 84 and 336 milligrammes, which gave readings of 100, 200 and 400 volts per division. The method of calibration employed was a direct comparison with an absolute electrometer of MM. Abraham and Lemoine. The result was a curve which was sensibly proportional from 0 to 18,000 volts, though somewhat convex between 0 and 4,500 volts.

Electric Traction at Rouen.—Rouen has followed the good example set by Havre in 1894, and has recently converted its system of horse tramways into an electric network. The work was carried out by the French Thomson-Houston Company, and the line came into operation on the 22nd of last month. The total length of line amounts to 37 kilometres, 25 kilometres of which previously existed. Broca rails, weighing 44 kilogrammes per metre, are used, the gauge being 1·44 metre, and the maximum gradient 5 per cent. The power house is situated on the banks of the Seine, and comprises four Babcock and Wilcox boilers having 160 square metres heating surface, a Green economiser, three Corliss-Farcot single cylinder engines running at 70 revolutions, each belt driving a Thomson-Houston 200-kilowatt dynamo, over-compounded for 550 volts at full load and 500 volts on open circuit at a speed of 425 revolutions. There are the usual dynamo instruments and feeder panels on the switchboard. The feeders, four in number, have a total length of 6 kilometres, their sectional area being 200sq. mm. The return conductors are of bare copper, and have a sectional area of 150sq. mm., and are laid in wooden troughs filled with bitumen. The trolley overhead line is of bare copper wire of 8·25mm. diameter, and is suspended from iron poles 7 metres high. The cars, 60 in number, each carry 24 passengers inside and 16 out. They weigh 7 tons and are 8 metres long. Each car is driven by two motors of the Thomson-Houston type, built at the works of the Postel-Vinay Company at Paris. These motors are rated at 25 H.P. each, and are hermetically enclosed in cast steel casings. Single reduction gearing is used.

CORRESPONDENCE.

RÖNTGEN RAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is a mistake to suppose that the action of X-rays on a film is dependent on the glass backing, so that no action can be got on a ferrotype plate.

The truth is that a ferrotype plate is just about as rapid as a glass plate, though, of course, for practical purposes it is not so convenient.

Another fact is that extra thick films on glass are, as I expected, much better than thin ones.—Yours, &c.,

OLIVER J. LODGE.

University College, Liverpool, April 20, 1896.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: While experimenting with "X" rays obtained from a Jackson focus tube, the following results, which we venture to think of considerable interest, were obtained.

It seemed possible to cause the tube to pass through two distinct conditions. Starting with a spark of about two inches, and a fairly low vacuum, we noticed that the tube became generally luminous and filled with a bluish green haze, while brilliant green flickering patches appeared upon the glass. Under these conditions a screen prepared with potassium platino-cyanide glowed brightly when held near the tube, but shadows of the bones of a hand did not appear strongly marked upon it. The length of the spark was then increased, and while the screen became more and more brilliantly fluorescent, the shadows grew fainter, until a point was reached when there was scarcely any trace whatever of the hand upon the screen. The green patches on the tube were still visible, and the anode had become red hot, the screen was fluorescing vigorously, and yet practically no trace of the bone shadows could be seen. At this moment the spark was further increased, and the whole appearance of the tube instantly

Digitized by Google

changed. A vivid green mist filled the interior, all patches disappeared, the fluorescence gave a flicker and became slightly brighter, while at the same time deep shadows of the hand bones made their appearance. The effect must be seen to be fully realised.

It would seem then that during the first condition of the tube a radiation was given off which had the property of passing through bone, and thus behaving in a different manner to the "X" rays. What we call the second condition of the tube was reached, "X" rays were strongly given off, the bones appeared opaque, and the tube was in good order for obtaining "Röntographs."

As far as we have gone in the matter, it appears that a critical vacuum, together with a definite spark-length, is required to give the effect, and we would also suggest that a certain condition of the glass may be necessary. We have found, however, in several focus tubes which had been regarded as useless for the "Röntgen" effect, evidences of this peculiar radiation, to which even thin metals are considerably more transparent than to "X" rays. We hope to publish further results later.—Yours, &c.,

CHAS. E. S. PHILLIPS,
H. O. MANCE,
H. O'H. MOORE.

April 22, 1896.

[The curious phenomena observed by the writers appear to be precisely the same as those observed, for instance, by Prof. Silvanus Thompson, and communicated by him on April 7th to the Académie des Sciences (*Comptes Rendus*, Vol. CXXII., No. 14, p. 809). The concluding paragraph of Prof. Thompson's Paper reads as follows:—"By means of the fluorescent screen we are also able to show the heterogenity of the X-rays. With moderate vacua the X-rays do not penetrate the flesh to the exclusion of the bones as completely as do the rays emitted when exhaustion is pushed further. On the other hand, when exhaustion is carried very far, the X-rays not only penetrate flesh, but bone also. Hence there is a certain degree of exhaustion for which the difference in the transparency of flesh and bone is a maximum."—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is highly desirable that the exposures necessary for obtaining good results by means of Röntgen's photography when applied to the human body should, if possible, be reduced. This is not so important when it is merely a question of photographing the extremities, for which the necessary exposures are in any case now not very prolonged. Even in these instances, in the case of children, shorter exposures would be an advantage, but the question of reducing the exposures becomes of real importance, more especially in connection with the thicker portions of the body. Indeed, in order to ensure convenience and certainty in detecting calcareous deposits in the interior organs, for photographing the spine and such like purposes, a considerable reduction in the exposures now required is a *sine quâ non*.

Happily, there is every prospect of great improvements in this respect. The chemical action of the Röntgen rays upon a photographic film may be either a direct action or may be a secondary effect due to fluorescence of the film itself or of its support. In either case only a very small portion of the energy in the rays is photographically utilised under ordinary circumstances. This is clear from the fact that a large number of photographs may be taken at once by means of superimposed films, and also by the fact that if a photographic film mounted on celluloid be observed through a cryptoscope, it will be seen to be exceedingly transparent.

Nearly three months ago, in some remarks that I made at the close of Mr. Porter's demonstration at University College on January 30th, I suggested as a means of more completely utilising the energy of the rays, and thereby shortening the necessary exposure, the use of suitable fluorescent material applied either in the form of a screen behind the photographic film, or introduced into the substance of the film itself. Since then I have made numerous experiments in the direction indicated, and some weeks ago obtained conclusive evidence that by means of a screen thickly coated with potassium platino-cyanide and gum, placed behind a celluloid photographic film, the necessary exposure could be greatly reduced, also that in a less degree the same result could be obtained by the similar employment of a screen coated with powdered fluorspar. The chief objection to this method lies in the fact that it is very difficult to avoid granular results. Unless the fluorescent material be in a finely divided condition its grain shows distinctly, and mars the detail of the finished picture. The platino-cyanide does not work so efficiently when finely powdered as when in moderately coarse crystals, but good results can be obtained by thickly coating a thin celluloid film with an emulsion of this salt ground to fine powder in collodion, and using the screen so prepared with its celluloid surface in contact with the sensitive surface of the photographic film. I have obtained considerably better results with a finely-ground sample of tungstate of calcium, prepared for me by Messrs. Hopkins and Williams. This may be used either in loose powder or made up with gum into a paste and dried. With this substance it is easy to obtain sharp and fully exposed negatives of the hand in from 5sec. to 10sec. with a moderately excited tube, with which, with ordinary arrangements, 1min. to 2min. exposure would be necessary. I have also tried some special plates prepared for me by Messrs. Marion, into the sensitive emulsion of which fluorescent substances such as powdered fluorspar and calcium tungstate were introduced before application to the glass. Though the results so far obtained by this method are not very satisfactory, owing to granularity, the presence of the fluorescent substance in the photographic film appears undoubtedly to increase its sensitiveness to the rays. Apart from the question of granularity, the introduction of fluorescent material into the film does not appear to take away the sharpness of the result, and the same may be said with regard to the application of a fluorescent screen behind the film, provided the surface of such a screen is even, and is in very close proximity to the sensitive gelatine.

No doubt much experimenting remains to be done in order to obtain the best possible results.—Yours, &c.,

A. A. C. SWINTON.

66, Victoria-street, S.W., April 22, 1896.

PHOTOGRAPHS OF INCANDESCENT LAMP FILAMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I am not aware that experiments have been made to show whether or not certain substances—which in the solid condition at ordinary temperatures are non-transmitters of light—become transmitters of light by increase of temperature, say, to incandescence. Enclosed is a photograph of an incandescent lamp filament, taken by me a few days ago, and photographed by its own light.

The appearance is that where the filament crosses itself in the photo there is a brighter light given out. This would tend to show that the carbon became a transmitter of light when incandescent, so that the light from the rear portion of the filament penetrated the near portion, thus increasing the brilliancy at the points of apparent intersection of the filament with itself. The lamp was run off a 100-volt continuous-current circuit. This result may be of some interest to your readers.—Yours &c.,

ROBERT D. CASSELLS.

Glasgow, April 16, 1896.

Digitized by Google

[In order to show the effect better, we have had a careful drawing made of Mr. Cassells' photograph. In those places where the filament overlaps itself, either in part or in the whole of its width, the filament is shown quite white; in parts which do not overlap it is shown shaded. Owing to the hypothetical transparency of the filament the outlines of parts overlapped by other parts are drawn in, since on the hypothesis they would be visible.—Ed. *E.*]

THE ATKINSON REGULATING TRANSFORMER.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In reply to Mr. Atkinson's letter published in your issue of April 10th, we must admit, and apologise for, the omission in our Paper of any reference to the transformer patented by him at the end of 1889. At the same time his invention is only interesting as being, so far as we know, the first instance of a transformer in which the magnetic circuit was made moveable relatively to the secondary or primary coils. It is quite as unsuitable for use as a feeder regulator as Mr. Kapp's, illustrated in our Paper, Figs. 4 and 5. It will be seen by reference to the patent specifications that the "Manchester Edison-Swan" regulator works on a different principle, excepting that the magnetic circuit is moveable relatively to the secondary coils.

In reply to the last paragraph of Mr. Atkinson's letter, we have the authority of the Manchester Edison-Swan Company for saying that they have not arranged to make these transformers under licence from Messrs. Easton, Anderson and Goolden (Limited).—Yours, &c., Edw. W. Cowan.
Alfred Still.

THE PRODUCTION OF ALCOHOL FROM ACETYLENE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of April 17th there appeared an interesting review of Dr. F. B. Ahrens' monograph, "Die Metallcarbide und ihre Verwendung," in the course of which the writer reverted to the question of the synthetical preparation of organic compounds, such as alcohol, starting with acetylene (C_2H_2) prepared electrically as the base. The first step shown is the conversion of acetylene into ethylene, and the writer cites experiments following Berthelot's method of reduction by nascent hydrogen of the ammoniacal solution of copper acetylide, which, however, gave no result. For the purpose of effecting this first step, that is

$$C_2H_2 + H_2 = C_2H_4$$

Acetylene + hydrogen = ethylene,

Roscoe and Schorlemmer quote V. Wilde as stating in "Ber. Deutsch. Chem. Ges.," VII., 353, that platinum-black in contact with a mixture of acetylene and hydrogen brings about the combination of these gases, ethylene (C_2H_4) and ethane (C_2H_6) being formed.

The production of this latter body would also give an alternative method for the production of alcohol; thus

$$C_2H_6 + Cl_2 = C_2H_5Cl + HCl$$

Ethane. Chlorine. Ethyl chloride. Hydrochloric acid.

$$C_2H_5Cl + KOH = C_2H_5OH + KCl$$

Ethyl chloride. Potash = Ethyl alcohol. Potassium chloride.

—Yours, &c., Llewellyn B. Atkinson.

April 20, 1896.

DIRECT-COUPLED RAILWAY GENERATORS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In an editorial note published last week, with reference to the valuable and interesting series of articles by Mr. E. Tremlett Carter, which have recently appeared in *The Electrician*, we notice that you state that "there is not a single direct-coupled tramway or railway generator in the United Kingdom." Will you allow us to say that for some months past a 250 H.P. Willans engine, direct-coupled to a Siemens' dynamo, and running at 350 revolutions per minute, has been in daily work at the Stockwell generating station of the City and South London (Electric) Railway Company, where its running can be easily compared with that of belt-driving plant. We believe we are justified in saying that it has worked with the most complete success, and has afforded ample proof, if any is needed, of the suitableness of direct-coupled, high-speed plant for traction purposes, under the greatest variations of load. At one time the engine was exposed to such extreme variations that in the course of a few minutes the automatic cut-out would come into action several times, on each occasion making an instantaneous change from full (or excessive) load to no load at all. Under these circumstances there has been no tendency to race, nor has any trouble whatever arisen.—Yours, &c.,

C. S. Essex, Secretary,
Willans and Robinson (Limited).

LIGHT LOCOMOTIVES BILL.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The Light Locomotives Bill which was recently introduced in the House of Lords, is of such vital importance to the electrical industry that perhaps you will find space for the following.

Mr. Chaplin received the deputation headed by Sir David Salomons on February 12th, after which I had an interview with him, and I wrote to him at length on the following day. I need not, however, trouble you with my letter of that date, or Mr. Chaplin's courteous answer. When, however, on March 30th we were able to obtain a copy of the Bill I wrote to Mr. Chaplin a letter, copy of which I enclose, together with his reply. I am glad to be able to add that on Tuesday last Mr. Chaplin and Lord Harris did me the honour of receiving me at the Local Government Board. I found them most anxious to do all in their power to meet the reasonable requirements of all the industries interested in this particular Bill. They, however, are of opinion that it is essential some restriction should be placed on weight, as otherwise they fear that heavy traction engines will be run about the country and through our towns at a considerable speed. I am glad, however, to be able to add that though they were not able, until after consulting with their technical advisers, to determine the exact limit of weight that the Government may think necessary, yet I have no doubt when the Bill is read a second time in the House of Lords we shall find, instead of two tons, if not five, at any rate four, tons will be substituted. Mr. Chaplin said that this is a matter of experiment, and that the Government, while most anxious to assist the industries connected therewith in every possible way, felt that until some experience was gained on the subject they must be very cautious. Electrical omnibus traffic can certainly be conducted with success with a weight of five tons, and I have very little doubt that even if we are restricted to four tons, we shall be able to do very well with this traffic in our London streets and in other towns.—Yours, &c., S. Flood-Page.

102, St. George's-square, S.W.

[Copy.]

102, St. George's-square, S.W., April 1, 1896.

Locomotives on Highways.

Sir: I have the honour to remind you of the interview which you accorded me, after you had received the deputation on the above subject, on February 12th, together with my letter of February 13th, and the answer of your secretary thereto. I am afraid that in the multitude of the business connected with your department you have overlooked your kind promise to bear in mind my representation as to the vital importance to the electrical industry of not limiting the weight of the omnibuses or carriages to be used in towns to two tons. I may state that this limit, which is unfortunately contained in the Bill, has created great consternation amongst those connected with the electrical industry. It was only the day before yesterday that we were able to obtain a copy of the Bill, and I have already received communications from several of the leading representatives of electrical work, suggesting my writing to the papers, holding meetings, &c. I have, however, such confidence in your promise as to feel assured that such public agitation will not be necessary.

If this limit is maintained it will practically exclude the use of electricity for horseless omnibuses, though it is undoubtedly the safest, cleanest and best for such carriages.

On Wednesday last I was speaking at the meeting of the Associated Chambers of Commerce as one of the Council of the London Chamber, and remembering your promise that you would bear in mind my representations on this subject, I stated that we might look forward to the Bill with complete confidence that there would be no restriction put on horseless omnibuses not found necessary with the existing omnibuses, and no unnecessary interference with the natural development of the electrical industry as applied to omnibuses, &c., in towns. Judging from the welcome

Digitized by Google

this announcement received from the delegates of the Associated Chambers, I have no hesitation in saying that if it had entered into my mind that this prohibitory restriction of weight would have found place in the Bill, I should have been able to get a resolution passed unanimously asking you to withdraw your present limit if, in fact, you thought it essential that there should be any limit whatever or any restriction beyond that for street traffic in London at the present moment. You are aware that laden waggons of 16 tons are now legally permitted to traverse our streets, while the large three-horse omnibuses, weighing very many tons are allowed the free use of the Paris streets.

This question is one of such absolutely vital importance to the electrical ndustry, which, as you are aware, has been most seriously hampered in this country by what is now recognised as erroneous legislation, that I do hope you will be able to remember your most kind promise to give effect to my representations, and that you will prevent the agitation which must immediately be excited if this most lamentable, unnecessary and unjust restriction is maintained in the Bill.

Naturally I will not ask you to see me, with one or two other representatives of the industry, during the short Easter holidays, but I shall be most glad if before any public meeting is called, you would see me, with one or two representatives of the electrical and carriage-building industries, so that, if possible, the necessity for this agitation may be done away with.

I have the honour to remain, sir,

Your obedient servant,

(Signed) S. FLOOD-PAGE.

To the Right Hon. H. Chaplin, M.P., &c.

[COPY.]

Local Government Board, Whitehall, S.W., April 2, 1896.

Dear Sir: Mr. Chaplin desires me to reply to your letter on the subject of the Light Locomotives Bill.

The Bill has been introduced in the House of Lords in consequence of the pressure of other business in the House of Commons. The question of the weight of the articles to which the Bill is to apply is a matter of detail, and Mr. Chaplin is perfectly ready to receive and consider suggestions on the subject, which is a new one to all concerned, and of which there has been so little practical experience.

He has forwarded your letter to Lord Harris, who has charge of the Bill in the House of Lords, and from whom your suggestions will, he is sure, receive every attention.

When the Easter holidays are over Mr. Chaplin will be very willing to see you, in company with Lord Harris, or to receive in writing any further statement on the subject which you may like to submit.—Yours faithfully,

(Signed) H. C. MUNRO.

Combination Railway Generators.—The Akron, Bedford and Cleveland Railway, U.S.A., which was laid down last summer, is about 30 miles in length, and is, says the *Electric Railway Gazette*, provided with two power stations, one located about six miles from the Akron end, and the other about six miles from the Cleveland end. At present there are in operation eight double-truck cars, each being equipped with two Westinghouse 50 H.P. motors. A speed of over 30 miles per hour on the level may be obtained. Each station is equipped with two 250-kilowatt generators, constructed by the Westinghouse Company, and which are capable of furnishing either direct current for the operation of the road, or two-phase alternating current for power or lighting purposes. The machines are provided, in addition to the commutator for direct current, with four collecting rings and brushes for the two-phase current, the armature winding being tapped at suitable points by wires which pass through the shaft and are connected to the rings. When the machine is operated as a railway generator the main current passes through the series-winding as usual; if, however, the machine is to be used as an alternating-current generator, the terminals of the series-winding are connected across the brushes of a small commutator carried upon the shaft just outside the bearing. The current supplied to this commutator comes from independent coils wound on what may be called the spokes of the armature. These coils act as a secondary of a transformer, the primary of which consists of a few turns of winding upon the same spokes through which passes the alternating armature current. The current flow in the secondary increases and decreases in direct proportions to variations in the strength of the main current, and, being commutated and used to assist in the field excitation, the latter is increased in proportion to the load on the machine. The armature core consists of thin steel discs, and the field core is built up of thin steel plates cast into the iron yoke or frame of the machine. The generators have eight poles, and run at 450 revolutions. The normal E.M.F. at full load at the direct-current brushes is 550 volts, and that at the alternating-current brushes at full load is about 385 volts. The machines can be used as alternating and direct-current generators at the same time; but when so used they will not, of course, regulate for both loads.

LEGAL INTELLIGENCE.

Gaskell and Grocott v. Gosling.

This case again came before the Court of Appeal (consisting of the Master of the Rolls and Lords Justices Lopes and Rigby) on Wednesday for judgment, being an appeal by the defendants in the action of Gaskell and Grocott *v.* Francis and Cunliffe Gosling (reported in *The Electrician* of February 14th last, the original action being reported in our December 6th issue) from a judgment of the Lord Chief Justice. The plaintiffs are makers of porcelain parts of electrical apparatus, and carry on business at Longport, Staffs. Their action was brought to recover from the defendants (who are members of the banking firm of Gosling and Sharpe) £488. 9s. 3d., the price of goods alleged to have been sold and delivered between December, 1893, and January, 1895. The action raised the important question as to whether trustees for debenture-holders, who appointed a receiver to carry on the business of a company which was in liquidation, were themselves liable to pay for goods sent in to the Receiver. The goods in question were so supplied, and when payment was asked for it was said that the goods were supplied to the Company, and that the Company must be looked to for payment. Down to 1892 a firm called Poole and White (Limited) carried on business in Bread-street, London, and became indebted to Gosling and Sharpe for about £3,000, which was secured by a trust deed on July 22, 1892; the trustees certified that the debenture-holders' security was in peril, and thereupon the debenture-holders appointed a man named Kelly as Receiver. On September 1st a petition was presented by a creditor to wind up the Company, under which, on September 14th, a compulsory order was made. After the winding-up order the business was carried on by the man Kelly. In 1893 the plaintiffs called at the office and saw Kelly, and ascertained that the business was being carried on for the benefit of the debenture-holders, and from time to time they took orders and supplied goods to Kelly in his capacity, as they alleged, of Receiver. Three sets of debentures (amounting to £11,000) had been issued, for £7,000, £3,000 (those held by the defendants), and £1,000. But Kelly, being appointed on behalf of the second set of debenture-holders, it was not until February, 1895, that the first debenture-holders came in and turned him out. While Kelly was carrying on the business over £700 worth of goods were delivered by the plaintiffs, but by means of small credits that sum had been reduced to the amount claimed. The defendants denied liability on the ground that the trustees to the debenture-holders had, under their powers, appointed a man named Kelly as Receiver, who carried on the Company's business as the agent of the Company, and that under such circumstances the Company was liable, and, alternatively, if it was held that the winding-up order made in September, 1892, revoked the trustees' powers, then that Kelly was liable personally for the amount claimed. The Lord Chief Justice held that the defendants were undisclosed principals, saying that it was necessary for Kelly to obtain money or credit to carry on the business, and that when he was appointed Receiver he disclosed the fact that he was Receiver, and his Lordship gave judgment for the plaintiffs for the amount claimed, with costs, and against this decision the defendant appealed.

The MASTER OF THE ROLLS, in the course of an elaborate judgment, and after narrating the facts of the case, said that he held that the goods in question, which were all ordered after the time when the Company was in liquidation, were ordered by Kelly as the agent of Messrs. Gosling, the trustees who allowed him to act as their agent, and that therefore they were the undisclosed principals. He came with less hesitation to that decision when he considered that if the argument of the defendants was true they were reaping the profits of the plaintiff's goods without any liability to pay for them. If that was the law he could not help thinking that it was a dishonest law, and he came to the conclusion that the decision of the Lord Chief Justice was right, and that the appeal ought to be dismissed.

Lord Justice LOPES said that he was of the same opinion. Even assuming for the purposes of the case that up to the presentation of the petition Kelly was the agent of the Company, and that the Company were liable, he (his Lordship) came to the conclusion that after the winding-up order there was ample evidence to justify the Lord Chief Justice in finding that the defendants were the undisclosed principals of Kelly.

Lord Justice RIGBY said that he had the misfortune to disagree with the other members of the Court. In his opinion no control was exercised or stipulated for by the trustees over the Receiver, or if any was it was very insignificant. The Receiver was appointed for the very purpose of securing payments of interest to the series of debentures, and it was the duty of the Receiver to pay the interest if he had funds in hand to do so. The position showed, in his opinion, that at any rate down to the date of the winding-up order that the trustees had not taken a single step which would have even a tendency to make them responsible to the creditors of the business, or to the Receiver, and had no interest which would make them responsible. And no evidence was suggested of any interference by them after the date of the winding-up order. They no doubt could have made void the appointment of the Receiver, and have entered into possession, but so also could the trustees of the first series of debentures. Neither of them were under an obligation so to act or incurred liability in omitting to do so. He thought that the action against the defendants failed, and that the appeal ought to be allowed.

The appeal was therefore dismissed with costs.

A stay of execution was granted pending an appeal to the House of Lords.

Mr. Jelf, Q.C., and Mr. Hansell appeared for the appellants, and Mr. Herbert Reed, Q.C., and Mr. W. F. Hamilton for the respondents.

Swinburne and Co. v. J. D. F. Andrews and Co.

At the Westminster (London) County Court, on Monday, a case was heard in which the plaintiffs sought to recover payment in respect of a dynamo and arc lamps supplied to the order of the defendants. The plaintiffs' case was that they were instructed to make some arc lamps of a peculiar kind from drawings supplied by defendants, and in order to carry out the work a good deal of extra expenditure was incurred. When the order was completed application was made for payment, and it was alleged that not until the matter was put into the hands of the solicitors was any complaint made as to the goods being defective. For the defence it was contended that both dynamo and lamps were defective, and that the work had not been carried out according to instructions. It was further contended that the charge for extras which the plaintiffs now sought to recover were grossly exaggerated and contrary to the terms of the order. After hearing the evidence, the Judge said the plaintiffs' charges appeared to be somewhat heavy with regard to the extra work, and, without going into figures, he should give them judgment for £45 and costs.

Holdsworth v. St. Pancras Vestry.

In the Queen's Bench Division on Friday last, before Mr. Justice Cave and a common jury, Mrs. Elizabeth Holdsworth, wife of a plasterer, residing at Somers Town, London, sued the St. Pancras Vestry to recover damages for personal injuries sustained through alleged negligence. Counsel for the plaintiff stated that about eight o'clock on February 23rd, last year, she was in Gee-street, St. Pancras, when an explosion took place through gas having accumulated in the culverts and street boxes through which the defendants' electric wires passed. Immediately after the explosion she became unwell, felt pains in her head and lost the sight of the right eye, which was, however, restored. Plaintiff alleged that the defendants were guilty of negligence in not properly ventilating the culverts and road boxes, that the insulation was imperfect, and that in consequence of the defects in the defendants' distributing system, there was risk of an explosion if coal-gas got into the boxes. Defendants admitted the explosion, but pleaded that plaintiff was not injured by it, and also denied that they had been guilty of any negligence.

The jury ultimately found for the plaintiff for £105, for which sum judgment was given, but a stay of execution was allowed on condition that the money was paid into Court within a week.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

SPECIAL NOTICE—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d. abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices:—

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. The New Edition will be ready in a few days. Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free.

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables. 30s., post free.

"COMPREHENSIVE INTERNATIONAL WIRE TABLES FOR ELECTRIC CONDUCTORS."—By W. S. Boult, price 5s., post free.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated, will be ready first week in June.

TENDERS INVITED.—The Technical Education Committee of the Oldham Corporation desire tenders for the wiring of the Technical School in Ascroft-street, the installation consisting of 34 arc lamps, and specifications, &c., can be had from Mr. S. Wilmott Newington, borough electrical engineer, Gas-street, Oldham, and tenders must be sent to Mr. A. Nicholson, town clerk, the Town Hall, Oldham, by noon of May 1st. Some other particulars appear in our advertisement columns.

——— The Electric Light Committee of the County Borough of Oldham invite tenders for the supply of one 360 H.P. steam engine and dynamo. Specifications may be obtained from Mr. Arthur Andrew, Gas and Water Offices, Oldham, to whom tenders are to be sent by May 12th. Some further information is given in our advertisement columns.

——— The Public Lighting Improvement Committee of St. Helier, Jersey, invite communications from persons wishing to establish a lighting station in that town for the supply of electric, gas, or other forms of light for both public and private purposes. Communications should be sent to Mr. P. Baudains, Ecr. Constable, Town Hall, St. Helier, Jersey. Some further essential particulars will be found in our advertisement columns, and other information can be obtained on application to the Town Hall.

——— Tenders are required for the provision and fixing of electric bells, telephones, fire alarms, &c., at the Brook Fever Hospital, Shooter's Hill, S.E., for the Metropolitan Asylums Board. Copies of the specification (which has been prepared by Prof. Alex. B. W. Kennedy), forms of tender, &c., can be obtained at the chief offices of the Board, Norfolk House, Norfolk-street, W.C. Tenders must be delivered at the offices by 2 p.m. on Wednesday, May 6th. Further particulars are given in our advertisement columns.

——— The Electric Lighting Committee of the Coventry Corporation invite tenders for the supply and erection of (*a*) boilers and fittings, mechanical stokers and economiser, feed pump, &c.; (*b*) steam engine, alternator, oil filter, fittings, &c., steam, exhaust, feed, blow-off, and sundry pipes, valves, &c. Plans and specifications can be obtained from the consulting engineer, Mr. Robert Hammond, Ormond House, Great Trinity-lane, London, E.C., and tenders, addressed to the Town Clerk (Mr. Lewis Beard), St. Mary's Hall, Coventry, must be in by Tuesday, May 12th.

——— The Corporation of Sunderland require tenders for an evaporative tubular surface condenser, with air and circulating pumps. Tenders must be in by 5 p.m. on Wednesday next.

——— The Vestry of St. John, Hampstead, invite tenders for the supply, delivery and erection of a steam alternator, switchboard, steam and exhaust pipes, feed water heater, tank, and appurtenances, and these can be tendered for either as a whole or in part. Tenders must be in by 4 p.m. of the 27th inst.

——— Tenders are invited for the purchase of about 45 tons of old copper, a large quantity of other metals, india-rubber, and other old telegraph stores of the General Post Office. Tenders must be sent in to the Controller of Stores, G.P.O., St. Martins-le-Grand, E.C., by 10 a.m., Monday, May 4th.

——— Tenders are invited for supplying and fixing the necessary machinery for the electric lighting of the public baths and washhouses in Manor-place, Walworth, S.E. Tenders to the Vestry Clerk, Vestry Hall, Walworth-road, S.E., by 3 p.m. 29th inst.

——— The Société Nationale des Chemins de Fer Vicinaux, Brussels, invite tenders for electrically equipping about 20 kilometres of light steam railways in the centre district. Tenders to the Société, 26, Rue de la Science, Brussels, by May 27th.

——— Tenders are invited for the supply and installation of the plant and fittings required for the electric lighting of the steamer "Geheimer Baurath Wellmann" at Stralsund. Tenders to the Werft-bureau, Wasserbauinspektion, Stralsund, Germany.

Digitized by Google

TENDERS ACCEPTED.—The Bedford Urban Sanitary Authority have received the following tenders for the supply of a 240 B.H.P. double-acting compound engine and one 150-unit alternator :—

Engine and Alternator.

S. Z de Ferranti (Limited)	£2,350
Brush Electrical Engineering Company	2,253
D. Stewart and Co.	2,195

Alternator only.

Easton, Anderson and Goolden (*accepted*)	651
Siemens Bros. and Co.	1,250
John Fowler and Co. (Leeds)	1,090
Crompton and Co.	980
Mather and Platt	930
Manchester Edison-Swan Company	928
Electric Construction Company	903
Johnson and Phillips	850

Engine only.

W. H. Allen, Son and Co. (*accepted*)	700
G. E. Belliss and Co	1,050
W. Sisson and Co.	790

——— The Bedford Urban Sanitary Authority have also received the following tenders for the supply of cables :—

W. T. Glover and Co. (*accepted*)	£4,854 0 0
General Electric Company	8,280 17 2
Fowler-Waring Company	6,385 1 10
India-Rubber Company	5,652 1 3
Telegraph Manufacturing Company	5,572 12 11
Siemens Bros. and Co.	5,327 2 6
Johnson and Phillips	5,189 11 3
W. T. Henley's Company	5,119 8 11
Callender Company (not in accordance with specification)	3,912 13 6

The following tenders were also received for the construction of five underground sub-stations :—

T. H. Coleman (*accepted*)	£235 0 0
J. P. White	325 0 0
T. Langton	295 0 0
H. E. Tathersly	272 10 0

——— The Walsall Town Council have accepted the following tenders :—Walsall Electrical Company, arc lamps, £6 each ; W. Macfarlane and Co., arc lamp posts, £11. 14s. 6d. each ; Callender Company, extension of electric light mains.

——— The tender of the Glasgow Branch of the General Electric Company has been accepted for the supply of a dynamo required at the Dalmarnock Sewage Works.

MACHINERY, BOILERS AND OLD STORES FOR SALE.—The Eastern Telegraph Company announce that they have for disposal a large quantity of old stores, &c. List and particulars can be obtained on application to Room 320, Winchester House, Old Broad-street, London, E.C.

APPOINTMENTS.—Mr. Arthur Ellis has been appointed to the position of electrical engineer at Bolton, in succession to Mr. J. H. Rider, at a salary of £300 per annum. Mr. Ellis was apprenticed to Messrs. C. A. Parsons and Co. ; afterwards he held a position as second engineer to the Newcastle and District Electric Lighting Company. He was next employed by the Cambridge Electric Supply Company, being clerk of the works during the construction of the generating station of that Company, and on the retirement of Mr. G. Wilkinson from Southport he was appointed electrical engineer at a salary of £208 per annum.

——— Mr. G. H. C. Risch, jun., has been appointed electrical engineer to the West Ham Town Council. The salary is £300 per annum.

APPOINTMENTS VACANT.—The Directors of the Great North of Scotland Railway Company require an electrical engineer to undertake the duties of electric lighting and telegraphic superintendent. Salary, £250 per annum. Applications to the Secretary (Mr. W. Moffat), Aberdeen, by the 30th prox. Some additional particulars appear in our advertisement columns.

——— An assistant is required for the Physical Department of the City and Guilds Central Technical College, Exhibition-road, S.W. Salary £100 per annum. Applications to Prof. Ayrton. Some further particulars will be found in our advertisement columns.

——— A Principal is required for Sind College, Karachi, India, and will be required to teach physics and chemistry. Salary Rs.500 per mensem for 21 months, with £50 for passage. Applications to Dr. M. J. Jackson, care of Messrs. H. S. King and Co., 65, Cornhill, E.C.

——— The Technical Instruction Committee of the Borough of Plymouth require a Master for the Physics Department at the Technical Schools. Applications to the secretary, Mr. T. W. Byfield.

MEN WANTED.—The Gas Committee of the Borough of Salford require a switchboard attendant.——Two drivers of steam turbo machines are required.——An electrical engineer experienced in the running of Parsons steam turbines is required. Some particulars are given in our advertisement columns.

OBITUARY.—Mr. George Warren, for many years chief of the telegraphic department at Osborne, the Queen's Isle of Wight residence, died on Tuesday last.

PERSONAL.—Mr. Percy Dewhurst notifies that he has severed his connection with Mr. E. Dewhurst, of Preston and Blackpool, and that he has commenced business as an electrical engineer at 90, Church-street, Blackpool.

LIQUIDATIONS.—A meeting of some of the principal unsecured creditors in Woodhouse and Rawson United (Limited) met at the Bankruptcy Court, London, on Tuesday, to discuss as to whether proceedings should be taken against the directors, auditors, and other officials of the Company, to recover certain sums, which, according to the opinion of counsel, have been paid *ultra vires* in the form of over-paid commission and in respect of unearned dividends. It will be remembered that on the receipt of counsel's opinion, Mr. Stewart, late Official Receiver, invited the debenture holders in Woodhouse and Rawson United (Limited) to take steps to recover the sums referred to, amounting in all to £24,000 (£4,000 alleged overpaid commission, and £20,000 distributed in dividends, but, according to the opinion, not properly so distributed). The Ten per Cent. and the Six per Cent. Debenture holders declined to take any steps in the matter, and Mr. Justice Vaughan Williams then permitted the Official Receiver to place the matter before the unsecured creditors for their consideration, the Court deciding to allow the claim against the Directors and officials to be put up to tender. It was this proposal that the creditors met to discuss, and after consideration it was decided that steps should be taken to ascertain the opinions of the whole body of unsecured creditors, with a view to a tender being submitted by the Official Receiver, and subsequent proceedings being taken on behalf of the creditors. So soon as the amount of the tender is agreed upon it is proposed that a guarantee fund be lodged indemnifying the Official Receiver against all costs in any action that may be brought to recover from the Directors and officials the sums above set out. Creditors are invited on the receipt of a circular from a sub-committee appointed to deal with the matter to forward their comments and to set out the amount they are prepared to guarantee. The total liability of the Company to unsecured creditors is, we understand, about £15,000, and it is estimated that the amount of the necessary guarantee fund is not likely to exceed £500.

——— A meeting will be held at the office of Messrs. T. Horsfield and Co., 60, King-street, Manchester, on May 18th, at 3 p.m., to receive an account of the winding-up of Lowcock, Hill and Co. (Limited).

——— At a meeting of the proprietors of E. and E. Taylor (Limited), electrical and hydraulic engineers, on the 7th inst., it was resolved to wind up the Company voluntarily, and Mr. R. Harrison, 27, Chancery-lane, London, W.C., was appointed liquidator.

DISCHARGE IN BANKRUPTCY.—Mr. George F. Rogers, electrical engineer, of 41, Maxilla-gardens, Notting Hill, W., and 5, Great Winchester-street, E.C., intends to apply for his discharge on the 28th inst., at the Bankruptcy Court, Carey-street, W.C.

DIVIDEND.—A second and final dividend is payable at the office of Mr. J. M. MacLeod, 101, St. Vincent-street, Glasgow, on May 10th, in the bankruptcy of Messrs. D. and G. Graham, electrical engineers, late of Douglas-street, Glasgow.

MESSRS. CROMPTON AND CO.—We are now able to announce that this firm have secured a suitable site at Chelmsford for the erection of new works.

EXPORTS OF ELECTRICAL APPARATUS AND MATERIAL.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from April 9 to 21, 1896, with the ports of destination :—

Argentina—Pasages, £23,200 ; Rosario, £202. *Australasia*—Adelaide, £27 ; Auckland, £35 ; King George's Sound, £170 ; Melbourne, £78 ; Newcastle, £84 ; Otago, £62 ; Perth, £597 ; Sydney, £1,052 ; Wellington, £244. *Belgium*.—Antwerp, £218 (electric fuses) ; Brussels, £268. *Brazil*—Buenos Ayres, £12. *Canada*—Montreal, £18. *Ceylon*—Colombo, £128. *China*—Shanghai, £518. *Denmark*—Copenhagen, £13. *Greece*—Piraeus, £19. *Holland*—Amsterdam, £25 ; Rotterdam, £132. *India*—Bombay, £445 ; Calcutta, £1,093 ; Madras, £10 ; Rangoon, £12. *Japan*—Kobe, £324 ; Yokohama, £140. *Malta*, £1,196. *Portugal*—Oporto, £50. *Russia*—Revel, £65. *Siam*—Bangkok, £10. *South Africa*—Beira, £17 ; Cape Town, £514 ; Delagoa Bay, £100 and 34 tons iron telegraph poles ; Durban, £6 ; East London, £1,843 ; Port Elizabeth, £212. *Spain*—Bilbao, £20 ; San Sebastian, £20. *Straits Settlements*—Singapore, £25. *Sweden*—Stockholm, £251 ; Gothenburg, £137. *West Indies*—Demarara, £18.

Digitized by Google

Foreign-Made Electrical Apparatus and Material.—Foreign-made electrical goods to the value of £1,098 have been exported to *Australasia*: £288 to Brisbane, £135 to Sydney, and £675 (telephones) to Wellington.

TUDOR ACCUMULATORS.—There is just issued by Mr. A. B. Pescatore, of 5, Cross-street, Manchester, a useful price list of Tudor accumulators, accompanied by tabular statements of capacity, working rates, weights, dimensions and other particulars relating to both stationary and portable types. Users of these accumulators will find the general instructions issued with the list of service. Owing to an important improvement in the manufacture of the Tudor plates, a considerable reduction in the prices of these batteries is announced, especially in the case of stationary cells. The "S" type of cell, which is described in the catalogue, has been specially designed for isolated installation work, and the new portable cells have been perfected, type P.E. being specially designed for tramway work.

GENEVA EXHIBITION.—We have received an illustrated pamphlet entitled "Geneva and the Swiss National Exhibition," and containing some particulars of the forthcoming show, together with a general plan of the grounds. The exhibition will be opened on May 1st, and is arranged in 47 groups, in which will be displayed native industrial products. The machinery hall will be well provided with electrical apparatus of the latest type. There will also be an electric tramway, about 1½ miles in length, which will enable visitors to travel quickly from one part to another of the extensive grounds. M. Turrettini, the well-known engineer and Mayor of Geneva, is the President of the Exhibition.

PRICE LIST.—Lancashire boilers are far more extensively used in electric supply stations than the majority of engineers imagine; and they are to be found in some of the largest, best-worked and most economical stations throughout the United Kingdom. No less than 60 per cent. of the number of boilers in provincial stations are Lancashire boilers, and of these a considerable number have been made and supplied by Messrs. Tinkers (Limited), of Hyde, whose steel boilers are well known for excellence of manufacture. We have received a copy of a neatly-bound and illustrated price list of the Lancashire boilers and fittings made by this firm. The contents include a detailed description of the design adopted by Messrs. Tinkers in their boilers, price lists for boilers of various pressures up to 200lb., and some description of the boilers supplied by the firm for the Salford electric supply station. There is a good illustration of the somewhat cramped and crowded boiler house at this station. We have recently seen the particulars of some trials of steam plant, including this make of boiler, which testify to their excellent efficiency and steaming powers.

NON-SLIPPING STAIR TREADS, &C.—A useful catalogue is issued of Mason's patent "Unwearable" stair treads, man-hole covers, &c., which are manufactured by the Safety Tread Syndicate, of 15, Barbican, E.C., and Glasgow. It is scarcely necessary to point out the advantages of these treads, which have been supplied to the Tower Bridge amongst other important structures, and are in use in many of the principal Government offices. The treads are a combination of chilled steel, iron or other hardened metal with lead, the metals being so arranged that one withstands the wear while the softer gives the foothold, one of the many advantages claimed by the makers being that the treads are noiseless, as the lead is the only metal coming into direct contact with the traffic. Among the numerous manufactures of the Syndicate is a patent non-slipping iron ladder, which will be found of use for public lamp cleaners.

THE "JOURNAL."—Part 121 of the *Journal* is now ready (price 3s. 6d.), and can be obtained of the publishers, Messrs. E. and F. N. Spon, 125, Strand, W.C. The part contains the continuation and conclusion of the discussion of the Papers read by Messrs. F. Bathurst and Sam Mavor on the wiring question, Mr. G. L. Addenbrooke's Paper on "High-Voltage Lamps and their Influence on Central Station Practice," and Mr. E. Basil Wedmore's Paper on "A Simple Method of Analysing Periodic Curves," and also a classified list of articles on electricity and magnetism appearing in the principal technical journals during the month of February.

AYR.—At the last meeting of the Police Commissioners a letter was read from Mr. Ernest G. Pink, electrical engineer, in which he deals with the interruptions which have occurred in the supply of electric current. It will be remembered that three interruptions have happened—the first on March 26th, owing to a fault in the armature of the day-load exciter; a second on April 6th, owing to the load being too high for the day-load plant; and a third on April 10th of a more serious nature, the lights being out for 40 minutes. Mr. Pink is unable to assign any practical cause for the third extinction.

BAKER-STREET AND WATERLOO RAILWAY.—It is stated that the threatened opposition to the Bill promoted by the Baker-street and Waterloo Electric Railway Company has been withdrawn. The Company seek powers to construct a short extension of their authorised line so as to enable them to connect the system with the terminus of the M. S. and L. Railway Company. The additional capital required is £100,000.

BEDFORD.—After a lapse of 12 months the question of the electric lighting of the Shire Hall has again come up for discussion. The Bedfordshire Standing Joint Committee have now referred the matter to a special committee.

BELFAST.—A meeting of the City Council in Committee was held last week, when the Lord Mayor (Alderman Pirrie, J.P.) stated that the Special Committee recently appointed to meet the Belfast Street Tramways Company in reference to the question of the introduction of a system of electric traction had received the important proposals from the Company relative to the electrical equipment of their system and doubling the existing lines, which it is estimated would entail a capital expenditure of £200,000. This outlay would be expended in the following manner:—

1. Doubling single line (to be authorised by order in Council)...	£28,000
2. Doubling single line on Ligoniel and Sydenham lines	8,250
3. Purchase of these lines	20,000
4. Street work for electric traction, 23½ miles, at £2,200	51,700
5. Power plant	24,675
6. One hundred electric motor cars at £500 each	50,000
7. Widening existing lines to 6ft., purchase of County Down Railway Tramways and contingencies.....	17,375

If the term were extended to 21 years the Company would be willing to sell the Sydenham, Ligoniel and County Down Railway tramways to the Corporation on the same terms as their own, and withdraw their opposition to the Boundary Bill. In view of the large expenditure involved the Company could not see their way to introduce electric traction unless they obtained an extension of the term of their lease, but if the Corporation granted them an extension of seven years they would carry out the views set forth in the recent report of the deputation appointed by the Corporation to visit continental cities where electric traction was employed. After a two hours' discussion it was proposed "that the Council approve of the recommendation to permit the Company to get an amended Bill, the terms to be settled by the Town Clerk, but that none of its powers be exercised without the consent of the Corporation." An amendment declining to accept the Company's offer and refusing to grant an extension of the existing lease was carried, but on the suggestion of Councillor Woodside it was decided to print and circulate the Company's offer amongst the members of the Council.

BOLTON.—An elaborate report on the question of introducing electric traction on the local tramways has been prepared by the late Borough Electrical Engineer (Mr. J. H. Rider) and the Borough Surveyor (Mr. W. H. Brockbank) and is being considered by the joint sub-committee specially formed to consider and report upon the matter.

BRADFORD.—Mr. Rienzi Walton held a Local Government Board inquiry on Tuesday last into the application of the Town Council to borrow £40,000 for electric light extension purposes. In support of the application the Town Clerk (Mr. W. T. McGowen) stated that the Bradford Corporation were the first public body to adopt electricity as an illuminant. They established an electricity supply station in 1889 at an expenditure of £20,000, and the public were so pleased with the light and the price charged that in 1890 the works had to be extended at a cost of an additional £30,000, and again, in 1893, another sum of £30,000 was spent in extensions, making altogether £80,000, for which borrowing powers were obtained. £74,162 of this sum had been expended, and liabilities had been incurred for a further £3,514, leaving a balance of £2,332. As to the present loan, it was estimated that £2,600 would be required for the site, £11,500 for buildings, &c., £10,325 for machinery (£4,400 for engines, £2,650 for dynamos and £3,000 for boilers), and £7,000 for cables, the three-wire system being now adopted. Mr. A. H. Gibbings supplied the inspector with technical details, and referred to the constant and rapidly-increasing demand for current. There was no opposition to the application.

BRISTOL.—In April, 1895, a report was presented to the Town Council by the Electrical Committee recommending considerable extensions of the electric lighting area, principally with a view to supplying current for private lighting, in order to bring the output more nearly up to the capacity of the then existing plant at the station. Many of the extensions suggested were agreed upon, and an expenditure of about £10,000 was authorised. Recently the Committee have reported upon the result of these extensions, and shows that success has resulted from the policy adopted. Whereas in April, 1895, only 17,420 8 c.p. lamps were supplied, the number is now 28,210, and in addition applications have been received for a further 1,200 lamps. This larger output of current has naturally considerably reduced the cost of production per unit, and in addition, instead of having to ask the Council to provide in the general district rate for sums in aid of the undertaking

Digitized by Google

(as in 1895), it has been found unnecessary to ask for anything beyond the sum for the cost of street lighting, as all expenses for the repayment of loans and interest, working expenses and maintenance of the undertaking can now be paid out of revenue. The Committee are convinced that still more profitable results may be obtained by a further extension of the system for private supply, but as the output now approaches very closely to the maximum capacity of the plant, if such extension is made further capital expenditure will be required. The Committee have carefully considered the localities from which the most profitable results may be expected, and the electrical engineer, Mr. H. Faraday Proctor, has prepared an estimate showing that the cost of enlarging the station, purchasing additional machinery, and extending the mains to the localities suggested would amount to the sum of £75,000, and the Committee estimate that this would ensure an increase of lampage up to 76,000 8-c.p. lamps. The Committee ask the Council to approve their recommendations, and the matter is to be discussed at the next meeting.

Bray.—A deputation, consisting of Messrs. E. Garcke, S. Sellon, A. E. Porte and others, waited upon the Town Commissioners with reference to the construction of the proposed electric tramway. Mr. Garcke said he would satisfy the Commissioners that the British Electric Traction (Pioneer) Company were prepared to carry out the works and maintain the tramways in a manner satisfactory to them; but before incurring any expenditure, he would like to know whether the Commissioners were in favour of the principle of electric tramways. Should they give the scheme their support, the necessary capital for constructing the tramways would be forthcoming. The system they proposed to employ was the overhead trolley, which he thought most suitable for the town. A special meeting of the Commissioners will be held on Monday next to consider the matter.

Church Lighting.—St. Matthew's Church, Ealing, is to be wired for the electric light at a cost of £120. As the District Council have decided to supply current for the lighting of places of worship at a discount of 25 per cent., it is anticipated that all the other churches in the district will also adopt the electric light. ——The electric light was installed at St. George's Church, Worcester, more than 12 months ago, and one of the churchwardens now states there has been very litt'e difference in the amount paid for electric current during the past year and the average amount paid for gas in the preceding years, and if the larger area at present illuminated (the new church being larger than the former) be considered—to say nothing of the superiority of the light—the difference very trifling. This proves that, with economy and care, the electric light does not involve a very large increase of expense.

City and South London Railway.—This Company's Bill was down for reading in the House of Commons on Monday last, but its consideration was adjourned till this day (Friday). An amicable arrangement is stated to have been come to between the promoters of the Bill and the members who have been opposing it on behalf of the Church of St. Mary Woolnoth.

Cork.—At a recent meeting of the Public Works Committee, the engineer to the promotors of the Cork Electric Tramway Company having submitted amended plans and particulars of the scheme, the modifications were approved.

Electricity in Mining.—At the recent meeting of the shareholders of the Lancaster Gold Mining Company, the chairman said, in reference to the plant with which the Board intended to equip the mine, that, although they were convinced that electricity would play a great part in the mining operations on the Rand, yet they did not want to pin their faith entirely to it. The installation would be such that they would use electricity, and have steam as an auxilliary power. The hauling on the incline would be done by electricity, because it had been demonstrated on the Rand that hauling by this means on the incline is a success. The electrical plant would be on the three-phase system, which he thought was the best system for generating power and at the same time giving current for lighting purposes. A novel feature of the workshops would be that every tool would be driven electrically. The first cost of this plant was a little larger, but there was a gain in capacity, and the cost of maintenance would be reduced to a minimum.

Fire.—With regard to the report of a fire on the premises of the General Electric Company, Queen Victoria-street, London, this was a very trivial affair, damage to the extent of £2 only being done. Of course, business is not in any way interfered with.

Glasgow.—Mr. Primrose, at the last meeting of the City Council, referred to the recent report of the Special Sub-Committee on Street Lighting, and to the experiments that were now being carried out by that Committee. He pointed out that, as there was now a probability of the introduction of electric traction on the city tramways, a solution might be found of the question of the lighting of the leading thoroughfares by electricity, and that it might be found profitable to unite the street lighting with the development of their electric tramways.

Greenock.—At the meeting of the Police Board on Tuesday last a long discussion took place on a proposal to make extensions to the gas works. Dr. Calder and other members of the Board opposed the proposal, and contended that before going to any expense in the matter they ought to consider the question of lighting the town by electricity. The recommendation was, however, agreed to.

Grimsby.—The Town Council have at last decided to make a move in the electric lighting question. At the last meeting it was decided to refer the question of putting the Grimsby Provisional Order into force to the Lighting Committee, who are to collect information as to cost of establishing electricity supply works, and to report at an early date.

Halifax.—Mr. Rienzi Walton held a Local Government Board inquiry at Halifax on Wednesday into the application of the Corporation for sanction to borrow £20,000 for the purpose of extending the electric light works. The Town Clerk (Mr. K. Walton), in support of the application, said that the Corporation had already obtained borrowing powers for £39,950, and up to the present £43,355 had been expended. Current was being supplied to an equivalent of 12,000 8 c.p. lamps, and the demand was rapidly increasing. The deficiency on the first year's working was £1,090, including interest; but the works had been in existence only 15 months. Councillor Hebden opposed the application, on the ground that no provision had been made for developing electricity as a motive power in the town. The station plant was practically lying idle during the day; but if they could obtain a day load the Committee would be able to reduce the price to consumers. He contended that £5,000 of the £20,000 now applied for should be used for the purpose indicated by him.

Hospital Lighting.—The contract for wiring and fitting the new General Hospital, at Birmingham, has been placed with the Birmingham Electric Supply Company, and current for lighting as well as for power purposes is to be taken from the Company's mains.

Hotel Lighting.—Plans have been prepared for the erection of a new first-class hotel at Southend-on-Sea, which is to be lighted electrically throughout.

Lambeth.—A discursive debate on the electric lighting question took place last week at the meeting of the Vestry, when several resolutions were submitted for approval, amongst others, that the report of the Electric Lighting Committee recommending the transfer of the Vestry's Provisional Order to Mr. Sax be agreed to. An amendment that the report should be referred back was defeated, and the Committee's report was so far approved. The matter, however, did not end here, and after a lengthy discussion it was decided to again adjourn the subject to the next meeting of the Vestry, when eight further amendments await the members. Several public meetings have been held since the Vestry meeting, and at each a resolution condemning the action of the Vestry in this matter has been passed.

Lecture.—Mr. W. B. Sayers delivered an interesting lecture on the 16th inst. before the members of the Glasgow Philosophical Society on the "Domestic Applications of Electricity."

Liverpool.—On the recommendation of the Committee of Works permission has been given to the Liverpool Grain Storage and Transit Company by the Mersey Docks and Harbour Board to lay down plant for the electric lighting of their premises at the Alexandra Branch Docks.

Llandrindod Wells.—A hitch has occurred in the negotiations for the introduction of the electric light. The contractor, Mr. E. Davies, wants the Council to indemnify him against all actions that might be brought against him by private persons for breaking up the streets for laying down conduits and mains, but as the Council have declined to do this it is probable that work will not be commenced until a Provisional Order has been obtained.

Peterborough.—Electric lighting matters are making very slow progress indeed in this town. Some time ago the Council decided to issue circulars to the ratepayers in order to ascertain the amount of support likely to be accorded to their proposed electric light scheme, and in reply it was stated that between 1,400 and 1,500 8 c.p. lamps would be required, but no further steps were taken in the matter. Recently, however, fresh circulars were issued, with the result that considerably less than 1,000 lamps are now required. There is something wrong here; the ratepayers evidently are under the impresion that the members of the Council are not in earnest about their electric lighting scheme, and hence the decline of interest in it.

Portsmouth.—At a recent meeting of the Town Council, on the recommendation of the Electric Light Committee, it was decided to carry out various extensions of the electric light mains.

Presentation.—On the 16th inst. Mr. J. H. Rider, late borough electrical engineer of Bolton, was presented by some of his friends

Digitized by Google

with a valuable non-magnetisable gold watch in recognition of services rendered in connection with the introduction of the electric light into that town. The presentation was made by the Chairman of the Gas and Electricity Committee (Alderman Miles), who complimented Mr. Rider on the ability displayed by him in the management of the electrical department.

SHIP LIGHTING.—The recently launched P. and O. steamer "India" has been supplied with a very complete electric lighting installation by Messrs. Siemens Bros. and Co.——Baron Barreto's new yacht has also been fitted up for the electric light, the electric lighting machinery being supplied by Messrs. Laurence, Scott and Co. (Limited).

STOWMARKET.—The Urban District Council have given Messrs. Pedder and Prentice permission to erect a small electricity generating station at Stowmarket to supply current for public and private purposes.

STAFFORD.—The price of current has been reduced from 8d. to 4d. per unit for all current used above an average maximum demand of three-quarters of an hour per day during the summer.

SURBITON.—At the last meeting of the District Council an application was received from the Artisans' Land and Mortgage Corporation for permission to take electric current from the mains of the Kingston Corporation to light certain houses in the Surbiton district. The Clerk was instructed to reply that consent would not be given at present, as the Council had not yet decided as to whether they should themselves establish electricity works.

THORNABY-ON-TEES—Some time ago we animadverted on the attitude taken up by the Stockton Corporation and their gas manager (Mr. Ford) towards the electric light. Mr. Ford is of opinion that "at any moment an invention might take place which would infinitely cheapen the lighting of towns by electricity." There is evidence, however, that this excessive caution is not appreciated by the Corporation's probable customers. At the last meeting of the Thornaby-on-Tees Town Council Mr. Walker moved that a committee be appointed to consider and report upon the present supply of gas within the borough, and also to consider the advisability of making arrangements with any corporation or company for the supply of electricity for lighting purposes. On the suggestion of Alderman Anderson the motion was altered so as to refer the whole question to the General Purposes Committee, and in this form it was passed by a large majority. While the Stockton Corporation's gas engineer is making up his mind important probable customers are taking steps to supply themselves with current. This is hardly a dignified position for an important local authority to assume, more especially as the Stockton Provisional Electric Lighting Order was obtained so long ago as 1890.

TRAIN LIGHTING.—Following the lead of the North British and the Great Northern of Scotland Railway Companies, the Caledonian Company are now making some experiments as to the suitability of electricity for train lighting.

WORCESTER.—The City Council have decided to make a charge of 1½d. per unit for all current supplied to the Water and Sewage Committee for working the motors for pumping at the waterworks. The price hitherto charged has been 1d. per unit.

WORKS LIGHTING.—The Raleigh Cycle Company have decided to erect new works at Lenton, near Nottingham, and arrangements have been made to put in a very complete electric lighting installation at an early date. It is calculated that over 5,000 incandescents will be required.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

April 2, 1896.

7,174. J. C. GREEN. Winnipeg. A metal for heating by electricity.

7,195. S. Z. DE FERRANTI. London. Improvements in dynamos.

3,032. KRAPF. Electric railway signalling apparatus.
3,082. CUSHMAN. Armatures for induction motors.
3,093. DEVONSHIRE (Knight and another). Dynamo-electric machines.
3,094. DEVONSHIRE (Berg). Regulating alternating currents.
3,682. SIEMENS BROS. AND CO. (LIMITED) and KINGDON. Electric switches.

COMPANIES' MEETINGS AND REPORTS.

Oriental Telephone and Electric Company (Limited).

The second ordinary general meeting of this Company was held on Wednesday at the Cannon-street Hotel, London, Mr. Wm. Addison presiding.

The SECRETARY (Mr. Alexander B. Chalmers) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Before moving the adoption of the report and accounts I may congratulate the shareholders on the satisfactory progress that has been made by the Company, and especially on the realisation of what has been for years the hope of your Board in being able to recommend out of the net profits of the year a dividend at the rate of 5 per cent. With reference to the loss of our exchange in Colombo, of which the report makes mention, the Board has been throughout the year in continuous negotiation with the Government of Ceylon, which had already given us notice that it would not renew our licence about to expire at the end of December, 1895. Speaking with all the respect due to a Government, I am bound to say that we have been treated in a manner very discouraging to private enterprise, and unfair to a Company which had invested a considerable sum of money in the Colony, and was ready to invest still more freely if only it could have obtained continued security from the Government; nor have the Directors received that measure of support from the Colonial Office which, under the circumstances, they think they were entitled to ask. In the end the Board had to accept a sum which represents only a small part of the value of the exchange, upon which had been spent in cash £4,856 odd, to which must be added goodwill and compensation for forcible dispossession. If you look at the balance sheet you will find that the suspense account, in regard to the Colombo exchange, amounts to £2,481 odd. This amount could easily be liquidated by the profit on the Consols we hold, if they were to be sold, together with the amount now proposed to be carried forward, and after paying the dividend now recommended; but as the matter has only been finally closed within the current year, the Directors have thought it best to carry the amount to a suspense account, leaving its ultimate adjustment for future consideration. I have nothing further to add to the report; but before formally moving the adoption of it and the accounts, I shall be pleased to answer any questions any of the shareholders may desire to ask.

Commander HUGH H. HANNAY, R.N., animadverted on the shabby manner in which the Government of Ceylon had behaved to the Company in the matter of its plant. In view of the fact that the Company had bought its holding of Consols at about 96, which now stood at 113, had the Directors taken into consideration the advisability of selling the same and thereby making a profit of £2,000? He did not know whether it would be wise to do so or not; he wished merely to throw out the suggestion.

The CHAIRMAN, in reply, said that the Board had had the subject under consideration, but had not acted in the matter because they did not know what to do with the money, seeing that all other kinds of securities had risen in the same proportion. He then formally moved:—

"That the Directors' report, together with the accounts and balance sheet to December 31, 1895, be approved and adopted, and that a dividend of 5 per cent., free of income tax, be declared upon the paid up capital of the Company for the year ended December 31, 1895."

Mr. HENRY GREWING seconded the motion, which was carried unanimously.

In reply to Mr. Hibbert, who advocated that the shareholders should be called together at least twice a year in order that the Company's affairs might obtain greater publicity, and thus increase probably the value of its property in the market, the CHAIRMAN said that the Directors would take the subject into consideration.

On the motion of the CHAIRMAN, seconded by Mr. THOS. LLOYD,

Mr. Benjamin St. John Ackers was re-elected a Director of the Company, as was also Mr. G. B. Frost, on the motion of the CHAIRMAN, seconded by Mr. H. GREWING.

Messrs. St. John Ackers and Frost having expressed their warm acknowledgments,

Messrs. Deloitte, Dever, Griffiths and Co. were re-elected auditors of the Company for the current year, on the motion of Commander HANNAY, seconded by Mr. SEAMAN, and the proceedings terminated with a vote of thanks to the Chairman and Directors.

Telephone Company of Egypt (Limited).

The thirteenth ordinary general meeting of this Company was held on Tuesday, at the offices of the Company, 14, Austin-friars, Gen. Alexr. Fraser, C.B., R.E., presiding.

The SECRETARY (Mr. Alex. B. Chalmers) read the notice calling the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: You will see from the report that the credit to revenue account for 1895 is £4,821. 3s. 10d. The concessions made to the Government in the beginning of the year caused a considerable loss of income, but we hope that increased business will more than cover that loss in the course of time. The balance of £4,821. 14s. 3d., together with £1,254. 3s. 10d. brought forward from 1894 leaves the sum of £6,085. 18s. 1d. for disposal. Of this we propose to place £1,500 to a reserve account, to which we also transfer £3,000 detailed in the balance sheet of December, 1894, to contingency and suspension account, to pay a dividend of 6 per cent. on the Preferred shares, and to carry forward £964. 12s. 1d. The concessions alluded to above carry with them a contract with the Government for ten years' service from January 1, 1895. Our relations with the Government have been, happily, of the most satisfactory character, and we have offered to do all we can to assist it in its military operations. We have placed our agency in Egypt in the hands of Mr. Edward I. Manak, who had done good service for the Company in the past, and who, we hope, will justify his appointment in the future. Our staff, under Mr. Evans, the general manager (especially Mr. Stevenson at Alexandria), have done work worthy of your thanks, while Mr. Chalmers, the secretary, and his staff in London have, by their ability and assiduity, successfully coped with an increasing business. It will be gratifying to you to observe that the litigation alluded to in our last report has been again given in appeal in the Company's favour. I now have to propose the adoption of the report and accounts, and the approval of the declaration of the dividend set out in the report.

Mr. THOMAS LLOYD seconded the motion, which was carried unanimously.

The CHAIRMAN then moved the re-election of Mr. Thomas Lloyd as a Director, which was seconded by Mr. H. GREWING, and carried unanimously.

The auditors (Messrs. Price, Waterhouse and Co.) were reappointed, and the Directors' remuneration voted at £350 for the current year, after which a cordial vote of thanks to the Chairman terminated the proceedings.

The report of the Directors for the year ended December 31st last was as follows:—

The revenue shows a credit balance of £4,821. 14s. 3d. transferred to profit and loss, which, with £1,254. 3s. 10d. brought forward, gives £6,085. 18s. 1d. for disposal. The Directors propose to place £1,500 to reserve, transfer to the same account £3,000 credited last year to contingency and suspense account, and to pay a dividend of 6 per cent. on the Preferred shares, and to carry forward £964. 12s. 1d. The Egyptian Government having requested a revision of the charges made by the Company for conducting its telephone service, an agreement was entered into last year whereby the Company made liberal concessions to the Government on a contract for ten years, commencing January 1, 1895. These concessions involved a large decrease in the amount received from the Government for the past year, but the Directors hope that, eventually, the increase of the general business may compensate for this loss. The exchange at Mansourah was reopened on December 27th, and other important extensions are in view which, it is hoped, may be carried out during the present year. The exchange at Cairo is being remodelled, and new switchboards of an improved pattern are in course of erection. The litigation in which the Company was involved resulted in an appeal being made by the plaintiff; judgment, was, however, again given in favour of the Company, which closed the matter finally.

Eastern Extension, Australasia and China Telegraph Company (Limited).

The report of the Directors of this Company for the half-year ended December 31st last, to be submitted to the forty-fifth ordinary general meeting, to be held at Winchester House, London, E.C., on Wednesday next, at two o'clock, states that the gross receipts, including Government subsidies, have amounted during the period to £311,582. 10s. 11d., against £261,322. 14s. 6d. for the corresponding period of 1894. This large increase is mainly due to the exceptionally heavy traffic transmitted to and from Western Australia in connection with the gold mining industry that has recently sprung up in that colony. The working and other expenses, including £20,713. 2s. for cost of repairs to cables and expenses of ships, absorb £84,044. 6s. 4d., against £89,740. 14s. 9d. for the corre-

Digitized by Google

sponding period of 1894, leaving a balance of £227,538. 4s. 7d. From this is deducted £4,318. 8s. 4d. for income tax, £20,000 transferred to the fire insurance fund, £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, leaving as net profit £171,324. 16s. 3d., which, with £70,504. 13s. 3d. brought forward, shows an available balance of £241,829. 9s. 6d. One quarterly interim dividend of 1¼ per cent. has been paid, and it is now proposed to distribute another of like amount on the 30th inst., making, with the interim dividends paid, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share (or 2 per cent.), making a total distribution of 7 per cent. for the year 1895. The balance of £129,329. 9s. 6d. has been carried to the general reserve fund, which now stands at £561,546. 9s. 9d.

During the half-year the Company's system has been strengthened by the renewal of 340 knots of the New Zealand (original) cable and 109 knots of the Tasmanian (original) cable. The cost of these renewals, amounting to £38,733. 5s. 10d., has been debited to the general reserve fund, together with £186,043. 14s. 1d., the balance of cost of the alternative Singapore-Hong Kong cable. Further extensive renewal work will have to be carried out during the year.

During the half-year 409 of the Company's Five per Cent. Australian Government Subsidy Debentures, amounting to £40,900, were drawn by lot for payment at par on July 1st next.

With a view to placing the Company's tariffs on a more uniform and satisfactory basis, the Directors have decided to reduce the local rates as and from July 1st next. The immediate effect will certainly be a considerable falling off of revenue, but it is hoped thut the lower rates will lead to such an increase of business as may eventually recoup the initial loss.

Mr. John Denison Pender and the Most Hon. the Marquis of Tweeddale offer themselves for re-election as Directors, and the retiring auditors, Messrs. Deloitte, Dever, Griffiths and Co. and Messrs. Welton, Jones and also seek re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED.—The annual return of this Company, made up to February 21st, has just been filed. The nominal capital consists of £7,000,000 stock, which is fully paid up.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED).—The annual return to April 9th has been filed. Out of a nominal capital of £75,000 in £1 shares, 50,000 shares have been issued as fully paid. Share warrants comprising 10 shares each are outstanding to the amount of £4,020.

CHLORIDE ELECTRICAL SYNDICATE (LIMITED).—The annual return to January 14th has only just been filed. The capital is £262,500, in 110,000 "A," 140,00 "B," and 12,500 "C" shares of £1 each. All the "A" and "C" and 100,000 "B" shares have been taken up, and 45,000 "A," 100,000 "B," and 12,500 "C" shares have been issued as fully paid. The full amount has been called and paid on the remaining 65,000 "A" shares.

CRYSTAL ELECTRIC LAMP COMPANY (LIMITED).—The annual return to January 6th has only just been filed. The nominal capital is £15,000, in 1,000 Ordinary, 1,600 Preference "A," and 400 Preference "B" shares, of £5 each; 1,000 Ordinary, 1,001 Preference "A," and 400 Preference "B" shares have been taken up, and all the Ordinary and Preference "B" shares have been issued as fully paid. The full amount has been called on 1,001 Preference "A" shares.

DIRECT ELECTRIC GENERATOR SYNDICATE (LIMITED).—This Company has entered into an agreement with Messrs. C. P. Shrewsbury, J. Cooper, F. L. Marshall and J. L. Dobell, for the acquisition of letters patent Nos. 8,759, 9,108, 9,569 and 14,181 (1892), No. 12,483 of 1894, Nos, 8,306, 8,876 and 20,843 (1895), and also provisional specifications 13,110 and 15,782 (1894), for the sum of £95,000, payable by the allotment of 95,000 fully paid shares of £1 each.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The annual return to April 7th has been filed. The nominal capital is £95,000, in 13,000 Ordinary shares and 6,000 Preference shares of £5 each. 12,931 of the former and all the latter have been taken up, and the full amount has been called and paid.

DOUGLAS SOUTHERN ELECTRIC TRAMWAYS (LIMITED).—The annual return to March 5th has been filed. The nominal capital is £50,000, in 30,000 Preference and 20,000 Ordinary shares of £1 each; 12,166 of the former and 5,904 of the latter have been taken up, and the full amount has been paid.

HASTINGS AND ST. LEONARD'S-ON-SEA ELECTRIC LIGHT COMPANY.—The report of the Directors of this Company states that there was an increase in the income from public and private lighting of £1,271 for the past year, but it has been found necessary to debit the accounts with the loss sustained on the sale of installation stock, and also the bad and doubtful debts in connection with the late installation business. The Directors, however, believe that with careful management, and a strict control on the expenditure, next year's working will show good results, and with that view they have written off every loss. With the view of increasing the popularity of the electric light the Directors have for some time given a continuous supply of current, and hope it may be possible to continue such supply, it having been greatly appreciated by numerous customers. The arc lighting of the sea front has not proved remunerative, and if the contract is renewed in June next year it must be on terms more favourable to the Company.

CITY NOTES.

MEMORANDA—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31d. per oz. (April-23rd). Consols (2¾ per cent.) 112⅛–112⅜ for money, 112⅛—112⅜ for account; 2½ per cent. 105¼—105½ (April 23rd). Stock Exchange Settling Days: Consols, May 4th; Stocks and Shares Continuation Day, April 27th; Ticket Day, April 28th; Pay Day, April 29th; Mining Share Carry-over Day, April 25th.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—The fifth drawing for payment of 120 Four per Cent. Mortgage Debentures of this Company will take place on Friday, the 1st prox., at noon at the offices of the Company, Winchester House, Old Broad-street, London. The third drawing of the Four per Cent. Registered Debentures (Series "B"), 15 in number, will take place on the same date and at the same place.

BRITISH MOTOR SYNDICATE (LIMITED).—A statutory meeting of this Syndicate was held last week at which Mr. Harry J. Lawson, chairman of the Company, presided. Mr. Lawson referred to the dividend of 10 per cent. now declared as the first ever made in the horseless carriage industry, this being at the rate of 30 per cent. per annum. He announced that the Company were purchasing all patents put before them which a committee of experts recommended as likely to secure a motor monopoly to the Syndicate.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended April 19th were £921, against £856 in the corresponding week of 1895, an increase of £65. The total receipts for the half-year amount to £15,260, against £15,218 for the corresponding period of 1895, an increase of £42.

CONTINENTAL METROPOLITAN TRAMWAYS COMPANY (LIMITED).—The report of the Directors states that the question of the substitution of mechanical for horse traction has now reached an important stage, as the Paris municipal authorities have asked the various tramway companies for information as to terms (other than that of the extension of the concession) upon which they would agree to the general adoption of mechanical traction. The proposal of the Directors of this Company is the payment of an annual subsidy by the city, which would enable the Company to repay the necessary capital outlay within the period of the concession.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment by warrants on May 1st of interest for the half-year ending 30th inst. on their Four per Cent. Mortgage Debenture stock. The transfer books will be closed from the 27th inst. to May 1st inclusive.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment by warrants on May 1st of interest on their Four per Cent. Mauritius Subsidy Debentures for six months to 30th inst. The transfer books will be closed from 27th inst. to May 1st inclusive.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY (LIMITED).—The report of the Directors of this Company for the year ended December 31st last states that the whole of the £25,980 Second Debenture Stock has been redeemed, and 10,337 Ordinary shares have been handed in for cancellation. This has enabled the Directors to write off the deficit standing in the books and to reduce the patent account by £1,441. The amount due to the Company from Elmore's Metall Aktiengesellschaft is now £19,007. With regard to the latter Company's accounts the capital has been reduced to £30,000, in order that the loss standing to the debit of profit and loss should be written off, and the sum of £2,500 has been spent in new plant during the past year. The Directors state that the sales have been more than double those of 1894. The transfer of a loss in 1894 of £8 to a profit of £3,654 is notified. An important reduction has been made in the charges in the profit and loss account as compared with 1894, and the Directors are considering the means of still further reducing them. A loss of £1,575 is shown upon the year's working; but the Directors point out that this has been brought about by the large sum (£2,554) which has been written off as depreciation on the various assets. The average selling price of the Company's manufactures is stated to have been nearly £5 per ton higher than in 1894. It is proposed to put down 16 additional large tanks at an early date, and in order to pay for the new plant, the additional copper required, and to pay off the overdraft at the German bankers', it is necessary to make a further issue of Debenture stock. The report bears a striking resemblance to its predecessors, and the outlook for the Ordinary shareholders appears to be very little improved.

GENERAL ELECTRIC COMPANY OF AMERICA.—A New York correspondent states that the report of this Company for the year ended January 31st last shows a surplus over charges of $1,338,967. The charges for depreciation stand at $511,000, leaving a balance of $877,000, or sufficient to pay, if divided up, 3½ per cent. on the common stock.

LIVERPOOL GAS FITTINGS COMPANY (LIMITED).—The Directors propose to change the name of this Company to the Liverpool Gas and Electric Fittings Company (Limited), and a resolution authorising the change will be moved at the annual meeting on May 6th.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 19th inst. amounted to £1,151. The amount for the corresponding week last year, which included Easter Monday, was £1,386. Decrease £235.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended April 17th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,683.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended April 15th are £2,802, compared with £2,307 in the corresponding period of 1895. The December receipts, estimated at £5,103, realised £5,185.
